The "A B C" says, "The blacks are also easier to shake off combs in extracting time, and for that reason alone some prefer them, or hybrids, to pure Italians, which can hardly be shaken off." Prof. Cook says, "I have very little trouble to fell at one shake every Italian bee from the comb if the latter fully fills the frame." If Prof. Cook can shake *every* bee from the frame at *one* shake, he will confer a lasting favor on some of the veterans if he will make the process known. In spite of their shaking off so easily, he considers they stick tighter than the blacks, and prefers them on that account, for the best men stick closest to their homes. There are times when one wants bees to stick by their comb, and then he will prefer the tighter grip of the Italians; but at times when one wants bees to shake off, as in the case mentioned, will one not prefer that the bees he is trying to shake off shall shake off rather than stick on?

Prof. Cook says, instead of Mr. Benton spending years in India, he "was in India only a few days." In relation to this point I have a letter from Mr. Benton, who says, "I left Cyprus for India in December, 1880; returned to Cyprus in May of the following year—absent just *five* months." While the statement in the "A B C" was not strictly correct, Prof. Cook is no nearer the truth, for he has gone clear to the other extreme.

He thinks it unfortunate that the "A B C" uses the term "worm" and "grub" as synonymous with larva. That criticism is worth considering, at least so far as to avoid calling a bee a worm during its early life. Whether much more than that could be accomplished is questionable. To his credit be it said that Prof. Cook is consistent in that he does not speak of wax-worms, he calls them larvae or caterpillars. It is feared that, if a bee-keeper were to say that caterpillars had eaten up his combs, he might be laughed at. It is very likely, too, that for many years to come good scholars will say that wormy apples have worms in them. Moreover, when no entomologists are around, an insect-larva is a worm, for so the dictionary says. So is a larva of any insect a grub, by the same authority.

Instead of pollen and honey partially digested being fed to larvae, Prof. Cook says it is pollen perfectly digested, with or without the addition of honey. When doctors disagree, who shall decide?

Prof. Cook objects to calling "viper's bugloss" blue thistle. He says it belongs to the borage family, is no thistle at all, and is like borage in being no serious pest—all of which he should have noticed is already told in "A B C." But blue thistle is one of its popular names, so given in the dictionary.

He thinks droopes from laying-workers are as large as any, and it is likely that is true when they are reared in drone-cells.

"It is very doubtful indeed that unimpregnated eggs will ever produce workers," says the reviewer. It is not said in "A B C" that they ever will.

He thinks the word fecundate or impregnate should be used rather than fertilize. According to the dictionary, either is right.

Referring to feeding at night, Prof. Cook says, "Our author recommends this night work to prevent robbing." If he will read *carefully*, he will see that it is not recom-

APIARY OF FRANCES ELLEN WHEELER, OF CLINTON COUNTY, N. Y.

(Courtesy Reliable Poultry Journal.)

mended, only reported as being accomplisht, and that feeding toward night is recommended.

Prof. Cook believes the "A. B. C." wrong in teaching that honey from apple-bloom has a strong, rank taste like that from cherry-blossoms. He may be right; but this, like some other points to which he refers, was corrected in the edition just out.

In conclusion, we fear that Prof. Cook, overburdened with work like some of the rest of us, has not taken the pains to ascertain whether he himself is always correct upon all points. He is a pleasant writer—one whom the fraternity regards as authority; and whatever else we may say of him, he is actuated by the kindest of motives—a spirit that esteems others better than one's self.—Gleanings in Bee-Culture.

Advantages of Bee-Keeping for Women.

BY FRANCES ELLEN WHEELER.

IN the effort to encourage and lead women into rural occupations, there is a tendency to extravagantly exploit the advantages and minimize the difficulties; that is misleading and unfair. This is especially true regarding apiculture. Probably no industry has been more frequently and enthusiastically recommended to our sex than the care of bees. Certainly no outdoor work, in some respects, is so well adapted to our general make-up, or more thoroly fascinating and congenial. Thus far, our advisers are correct. Their mistakes arise from conveying to the novice an impression that the labor involved is of a light, superficial character, and that the profits are an assured fact, and to be confidently reckoned on. Some writers go still further, and state how many colonies the average woman can take care of alone, for an entire season, and what the returns will be for each colony.

Statistics look well on paper. Any one contemplating a new employment would feel better to know at the start just how much and how hard they must work, and what they will make at it. Some people are loath to undertake this enterprise unless they see in black and white the financial side of the question; which would be perfectly reasonable could the figures be relied upon. But in point of fact, there is scarcely any occupation where the unexpected is sure to happen, and the "unknown quantity" is so often to be reckoned with, as it is in an apiary; both as regards the labor involved and the profits received.

A little common-sense thought on the subject will show very plainly that no two women will do the same amount of work in an apiary (arg., more than they will anywhere else), or obtain the same results. And that in our country, where the climate and the local flora are so varied, the quality and quantity in the crop must also vary. Still more important,

the home markets range in prices according to locality for comb honey, all the way from 7 to 20 cents per pound; which affords quite a margin for speculation on returns. Moreover, is it fair to exact from this business what is not exacted from any other?

That an immense number of successful apiaries are scattered thruout our country is proof that bee-keeping pays. How near the "top notch" can be reached, each individual must demonstrate by practical experience. A good instruction book, a periodical, and a few colonies, at the start, will speedily tell the tale as to qualifications.

After a few experiences alone in the yard, our novice may decide (as I did) that it pays best, in the long run, to have a good, strong helper, and that to secure this when needed, some other industry must be combined with the apiary, which will give full occupation to both, and relieve the woman of the heavy parts; affording her leisure to oversee the important details, and attend carefully to her market.

Again, tho we have sections where the climate admits of an apiary being worked almost the entire year, it is not so in our northern and middle States. Also, our pasturage is such that there are many localities where apiaries of 80 to 100 colonies only can be worked, year in and year out, to good advantage. Yards of this size will not, of course, furnish an income sufficient for a comfortable living; but, with a comparatively small outlay of time and money, they will add very materially to it.

Something might also be considered of our returns which are not reckoned in dollars and cents. I refer to the growth in physical and moral health gained by the pure air and loveliness about us; the development of spiritual and intellectual perceptions; and, above all, the sense of helpfulness and fellowship with these wonderful little creatures; and commendation.

"Whatsoever thing thou doest,
To the least of Mine and lowest,
That thou doest unto Me."

Clinton Co., N. Y.

Something More About Bees Being Necessary to Pollenize Fruit-Tree Bloom.

BY THADDEUS SMITH.

THE advocates of the theory that bees are necessary for the complete pollenization of the bloom of fruit-trees lay great stress upon the necessity of cross-pollenizing and seem to think that bees are the only agents to accomplish this. By cross-pollenizing is meant that there are some varieties of fruit-bloom deficient in pollen, and the pollen necessary to fructify them must come from some other variety of the same fruit that produces more pollen. That there

are a few varieties of fruit deficient in pollen, is well known to all intelligent fruit growers, and they know equally as well that it is not necessary to have bees to accomplish this cross-pollenization, and do not depend upon them, but successfully manage it in another way. It is found that all that is necessary is, to plant these trees deficient in pollen, near some variety that produces pollen abundantly. In large orchards it is accomplished by planting the different varieties in alternate strips of several rows each, and thus complete pollenization is obtained without the intervention of bees.

A familiar illustration of where cross-fertilization is sometimes necessary is found in the strawberry. Every one who has planted a strawberry-bed knows that there are bearing and nonbearing kinds—pistillate and staminate varieties. The pistillate varieties do not bear pollen, and in order to make them fruitful they must be planted near the staminate or pollen-producing varieties. By planting the two kinds in rows from four to six feet apart, the pistillate—those without pollen—are made to bear fruit abundantly. The pistillate blossoms do not produce honey or pollen, and consequently are not visited by bees or other insects; therefore they are not fertilized by them. But suppose the bees did visit them—they could carry the pollen from one to the other just as easily if they were six rods apart instead of six feet. But they are barren or nearly so, if planted six rods apart. But proof positive that they do not owe their fruitfulness to bees is that both varieties have made fine crops on these islands where there are no bees. Such a fact is worth a dozen theories. If pollen can be carried in the air from one to the other of these lowly plants that creep upon the ground, to the distance of six feet or more, and successfully fructify the bloom, could it not be carried a greater distance and more successfully from the elevated position on fruit-trees?

Growers of vegetables in greenhouses have found that for want of circulation of air, some varieties of vegetables did not bear well; and some have been induced to try putting a colony of bees in with their plants, and have found some benefit from it. The benefit was not, primarily, caused by the bees carrying pollen from one flower to another on their legs or bodies, but was caused by the stir in the air, or the little breeze, as it were, that was made by the wings of the bees while gathering and transferring pollen to the little receptacles on their hind legs, that dislodged the pollen and set it in motion to be borne in the air to other plants. In feeding flour to bees early in the spring as a substitute for pollen, I have watched them with great interest while they were gathering and securing it in their pollen-baskets. They would gather the flour with their mouths and fore feet, and would sometimes wallow in it and get it all over their faces and bodies, and then they would rise, and with a peculiar fanning motion of their wings would keep themselves poised in the air just above the flour, while with their feet they were busy transferring the pollen from their front feet and bodies to the pollen-baskets, and by this motion of the wings they would create a little breeze that would blow all the flour off the board upon which it was fed. Pollen from flowers, whether in greenhouse or open air, is gathered and secured in the same way—placed in their pollen-baskets while on the wing, hovering over the flower, or while going from one flower to another, and as it is much lighter than wheat-flour, it is more easily dislodged and blown about in the greenhouse.

Up-to-date growers of vegetables under glass have long since discovered that the dislodging of the pollen and setting in motion could be accomplished without bees, and was equally as successful. They simply go thru the house with a light stick or rod and give each plant a gentle shake and the work of pollenizing is accomplished! This corroborates my statement, that the benefit from the bees was because they put the pollen in motion.

The ways of the propagation of species in the vegetable, insect or animal kingdom, is "wonderful and past finding out," but it affords a theme for interesting investigation which should be conducted in an impartial manner for the purpose of arriving at the truth. It is possible and I might say highly probable, that there may be some occult affinity or attraction between the stigma and the pollen of flowers by means of which the infinitesimal particles of pollen that are always floating in the air during fruit-bloom, are drawn as by a magnet, to the stigma when a short distance only from it; and when we look at the results—so few failures even under adverse circumstances—it seems there must be something of the kind. But this is speculation, and I am set for the defense of facts.

It is a fact that bees are seen in flowers with pollen on

their feet and in their baskets, and they are seen to leave one flower and go to another with their pollen; but who knows it to be a fact that some of this pollen obtained from the first flower is left on the second one visited? Is there any way of finding out? And if it were left, do we know that this flower would not have produced fruit without the visit from this bee? I have known millions of flowers to produce fruit that never had a bee within six miles of them. If they will produce fruit in one place without bees, why not in other places? This claim is all conjecture based upon preconceived theory without a knowledge of sufficient facts to establish it as a truth; and when confronted with such undisputed facts as I have given in regard to growing fruit in maximum quantities and qualities without bees, it shows its weakness.

Since writing the foregoing, the American Bee Journal of March 14th has come to hand, containing an article on this subject from Mr. G. M. Doolittle. Mr. D. represents himself as discussing this subject with a neighbor who claimed that Mr. D.'s bees had injured his fruit crop by taking the honey from the bloom, and he wanted some of Mr. D.'s nice honey to pay for the damage. Mr. D. tells how he met this claim by proving to his neighbor that his bees were of great benefit to his fruit, instead of being an injury; and here is a sample of his proof:

"Going back to the creation of all things, all fruit or grain of any kind was an entire failure till insects were created to visit the flowers which secreted nectar, while those that did not secrete nectar bore fruit as perfect then as to-day."

This certainly is a new revelation as to the creation of things. But Mr. D. explains that "thus far all is a matter of conjecture." But nevertheless he represents himself as telling it to his neighbor, supposed to be less informed about such matters, as a matter of fact. With his explanation the statement is most absurd, even as a "conjecture."

"So far," he says, "is conjecture," and then he proceeds to make some other assertions in this very remarkable article, that are equally as fallacious; tho he intimates that he is thru with his "conjectures," and has made no further explanation. "From this I go on to explain how that the first object of nectar in the flowers was not for the perfecting of the fruit, or to be used as a food or luxury for man, nor even to sustain the life of the bees, but as a means to an end, and this end was that insects of all kinds might be drawn to the flowers so secreting, that the fruit or female blossoms of plants which could not possibly be fertilized in any other way, might be fertilized thru the agency of insects," etc. Another new revelation—seed and fruit bearing plants and trees were made, but they "could not possibly be fertilized" so as to bring forth seed to propagate their species until honey was placed in the flowers and then bees made to go after this honey in order to fructify the flowers. In the quotation given, Mr. D. places "insects of all kinds" in italics, in order to emphasize the assertion. If language means anything this includes the festive mosquito, the agile flea, the night-prowling bedbug, *et id genus omne*. This is too ridiculous to require further comment.

I have great respect for Mr. Doolittle as one of our most reliable teachers and writers on bee-keeping, and I have read his articles in the bee-papers for the last quarter of a century with great interest; but when Mr. D. leaves the subject with which he is familiar, and gives us such crude speculation as this article contains, for matter of fact, we want a more reliable teacher.

Pelée Island, Ont., Canada.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one (of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto-queen-button that have been furnishing to bee-keepers for a long time. It has a pin on the underside to fasten to the coat. Price, by mail, 6 cents each; two for 10 cents or six for 25 cents. Send all orders to the office of the American Bee Journal.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Italianizing—Transferring—Painting Hives.

1. I have six colonies of black bees that did not swarm last season, but stored a little surplus honey, and have wintered in fair shape. Would it be good business to queen them with untested Italian queens? If so, at what time in the season should it be done? I do not wish to prevent them from swarming.

2. I have four colonies that are on frames that have thin top-bars that sag with the weight of the combs, and some of the combs are not built straight so they can be handled easily. Would it pay to transfer them to Hoffman frames with full sheets of foundation? If so, at what time in the season should it be done? There have been bees in the combs for 10 or 12 years. I wish to secure comb honey altogether.

3. Would it do any harm to paint hives with the bees in them? OHIO.

ANSWERS.—1. Almost certainly it would be a decided advantage to make the change. The only reason for putting in that "almost" is that it is a bare possibility that you have black bees that are unusually good, and that you would get Italians that are unusually bad. But that is very unlikely to be the case. The new queens can be given at any time when it best suits your convenience.

2. Most likely it would pay well to transfer to more satisfactory frames, whether Hoffman or something else is a question. If propolis is as plenty with you as with me, you will hardly want Hoffmans, but you can have frames that are self-spacing like the Hoffman without so much surface for propolis. But instead of changing the combs for foundation, why not transfer the combs into better frames? The age of the combs is nothing against them. The straight combs would be transferred very easily—do it in fruit-bloom—and it is possible that at least some of the crooked ones could be straightened, or put in piece-meal.

3. No, it will be all right, providing you make an arrangement with the bees that they will not sting the painter.

Clipping Queens—Other Management.

I expect to have about 40 queens to clip this spring. They are mostly in standard hives, but there was no brood foundation used, and I expect the combs are not in very good shape to hunt for queens.

1. How would it work, to place a hive filled with foundation in frames under a colony of bees (or perhaps have one frame of brood and a queen), place a bee-escape between the two hives, and below the escape have a cage of perforated zinc? Would the bees go down and accept the lower queen, and the upper queen attempt to go down and get caught in the cage?

2. Would there be danger of draining the upper hive so thoroughly that the brood would be left to chill?

3. If this plan would work, how long do you think it would take to trap the queen from the time the escape was placed, in warm weather? IOWA.

ANSWERS.—Instead of answering your questions in order, please allow me to bunch them. In the first place, unless you have queens "to burn," you may as well dismiss the idea of having a queen below. Your idea, no doubt, is to have the frame of brood and the queen there as a sort of attraction. Altho the brood would be to some extent an attraction, a strange queen would not. The probability, if not the certainty, is that she would be promptly balled and killed. Even if the bees should be friendly to the queen below, she would do no good. When there is a general stampede, and the bees leave the hive *en masse*, the queen goes with them. But in your scheme there is nothing of the kind. A bee leaves the hive in the regular course of its duties, and in doing so passes down thru the escape, and is unable to return. There is nothing about that to make the

queen want to go down. Neither is there when two bees or several thousand have gone down. All that she knows is that there seems to be getting to be a scarcity of bees, and that's no reason why she should desert her post in the brood-nest. So you may about as well give up the scheme as impracticable.

You do not say whether your object is merely to clip the queen, or to get the bees to move their brood-nest below. In either case, you can drum or smoke out the bees, hunt out the queen and clip her, then return. If you want the brood-nest to be moved below, put the queen in the lower story, with an excluder on it, then place over it the old hive. In three weeks time the worker-brood will be all hatch out above, and you can do what you please with the upper story. If you do not want to drum out the bees, you might proceed another way: Put under the hive a story filled with foundation (all the better if you can give it a frame of brood), with no excluder between the two stories, and allow the bees to work down of their own accord. As soon as the queen becomes crowded for room above, she will move downstairs, and when you find eggs there you may look for her. Possibly you may not find her, for until about all the space upstairs is filled with honey she will keep going from one hive to the other. But your chances of finding her below will be constantly on the increase, and after you do find her, if you want the brood-nest to be below, you must use an excluder.

Before doing anything else, it will be well to make a thoro investigation in each case, and see if you can not find one, two, or three frames that can be taken out, and then the rest might be cut out and transferred correctly into the frames.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.

By E. E. HASTY, Sta. B Rural, Toledo, O.

MATING OF QUEENS IN CONFINEMENT.

The front picture on No. 12 resuscitates an old enthusiasm, or fad, or "image of something in heaven above," at the shrine of which we all did vainly worship in time past—until the missionaries of common sense gently led us away. Possibly they were misguided in doing so. "Go in," Mr. Hutchinson! go in everybody who can't be entirely "asy" in mind about our present breeding! I feel quite strongly that the power to mate the individual drone to one individual queen would do us more harm than good; but the present scheme does not contemplate that exactly. It contemplates mating an individual queen to a nature-selected drone of a man-selected colony. More good than harm would come of that I think, providing success could be had. As Mr. Hutchinson suggests, success must be theoretically possible, providing some one is willing to spend effort enough, and cash enough, in building big enough. But let me also revive a related idea. Those who live near great plains on which there is no tree or hollow crevice, and no bees, can perhaps have the same thing cheaper. Take your wagon and drive out a few miles upon the plain, carrying your drone colony and your nuclei with virgins. Little islands are apt to be abnormally cool just when you want them to be hot; and at such stations queens drown; but plains incline to be hot at 2 p.m.

Possibly I can suggest some improvements on the tent shown in the picture. Suppose we abandon the gasometer shape, and let the starting model of shape be that of a race-track roof in—track only, center circle not occupied. Then flying around and around insects can go as many miles as they wish in a course that will not require any halting and turning back. Suppose we abandon the netting and use cheap cotton cloth. Abundance of light will come thru it; and it removes most of the temptation to butt in the effort to get out. Cheaper, much stronger, makes up on the sewing-machine more kindly, holes which may develop will be visible instead of invisible—better every way except perhaps the deadly didn't-think-of-it ones; and excepting the obvious objection that it will take more wind, and need to be more strongly supported. But with cloth cover and race-track shape I don't believe it will need to be more than 16 feet high. Presumably it will be possible to fly young queens and drones in such a course in ignorance of the fact that there is any

more to the world. Before you build, and after you have got this crude ideal of shape well in your mind, you can push in two opposite sides of it until it is dumb-bell shaped instead of circular—hives to be at one of the bulbs. This modification will save one wall, save very greatly in the ground area required, and give greater strength against wind. The cloth at the sides can be arranged to pull up and tie at the top when not in use and thus offer little sail to a storm.

It will require considerable grace to do so, but I trust Mr. Davitte will be able to take it meekly if there are still "Thomases" in the world. Sixteen days for preparatory exercise strikes one as rather a big chunk cut out of the drone's life. The words, "the queen and drone fall nearly to the ground," are provocative of suspicion. They sound so dreadfully like they were "cut out mit de shears" from the bee-literature of 25 years ago. A fall of less than 30 feet seems very inadequate to give time for twisting off a strong ligament by rotation. Page 181.

BECK-KEEPING AND PIANO-PLAYING.

Easier to learn apiculture than piano-playing, eh? Well perhaps. There's this about it—if you learn bees you suffer the torments yourself mostly; if piano is your choice the agony falls to the neighbors. Page 182.

ADULTERATION OF SUGAR COMMON.

Referring to Mr. Cowan's letter on page 211, I guess I shall have to admit that the adulteration of granulated sugar is getting to be common. Am using some now very pleasant to the taste, but nevertheless, tasting as tho there might be an admixture of something. The hardness of grain and the straight-out sweet and nothing else do not seem to be there.

BUCKWHEAT BLOOM EARLY.

West Virginia, on page 185—what does he want buckwheat to bloom July 1st for? Perhaps it might be well to tell him that buckwheat made to bloom abnormally early is pretty sure not to yield honey to amount to anything—also pretty sure not to produce very much grain, either.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

"THE BEST CROP."

At one of our recent farmers' institutes, a lady had a paper on the subject of "The Best Crop." Of course no one could know whether she was to treat of beans, barley, or beets. We soon found that it was to be none of these, but was to be devoted to the children. And surely she was right. The boys and girls do certainly form the best crop, not only of the farm, but of any home be it in city or country. I wonder if any of us realize this fact as we should. How many of the children use tobacco; how many even smoke the harmful, not to say deadly, cigarette; how many seek amusement in the saloon; how many use profane language; how many tell or listen to the vulgar story, and often demean themselves by telling it themselves. Oh, how happy we are if we can keep our dear ones from all these debasing habits! We engage men to spend days, and keep a close watch of them all of the time as they break a favorite colt. Yet do we all give time to the children, and do we watch as closely, as their habits are being formed? Do we give an hour or two on each Sunday, perchance walking in the field, park, or woodland, and calling their attention to the many beauties that are scattered so thickly all about us? The father and mother who have not had these pleasures have mist one of the rarest sweets of life. The children who have not in their early, tender years enjoyed this rich fellowship, have had a most valuable part of their life left out.

I do not think there is any one thing in my whole life that I recall with more satisfaction and genuine pleasure than I do the Sunday walks with the dear wife and children. I found it so easy to begot in the children a love even for the creeping, crawling things. They loved and admired even the snakes, the frogs, and the caterpillars. Who has not admired the stanza from the poet?

"He prayeth best who loveth best,
All things both great and small;
For the Lord God who loveth us,
He made and loveth all."

Can we help our children more than to lead them to love and admire God's handiwork at the very threshold of their lives? If we can couple with this in their young minds a full appreciation that all the good things are from God, we have given to them an invaluable possession. I would rather my child would have a perfectly realizing sense that God was all about him, loved him, cared for him, and was the Great Giver of all the beauty about us, than any other one thing. No father should be so busy that he could not take these Sunday walks with the dear children.

Is it not also true that the club or street-corner talk should be very valuable indeed if it robs the children of the time and sympathy of the father? How many fathers carry a life-long burden because of wayward children! I just heard a day or two ago of a good Christian man who lives close by us, who has also been a life-long minister of the gospel, whose son has dived into all the bad things that smirch the life and character. I have known the boy, and his face tells the story of his reckless life. I believe all this burden of sorrow might very likely have been avoided had the father found time during the boy's early years to have taken walks, read to him the Youth's Companion or other good paper, given him some chickens, and then taken the interest in him that is always so pleasing to the boy or girl.

I remember once in a lecture before the Chautauqua Association, in speaking of inclining in children a love of Nature, I made what I feared at the time was a rash assertion. I said that I believed that up to twelve years of age, if Barnum's "Greatest Show on Earth" were to come our way, and go to said to my boy and girl, "We will take the day off, and go to the circus or for a walk in the woods—which shall it be?" I believed that they would have elected the walk in the woods. As I thought me of the circus, the fine horses, the rapid and dizzy riding, the wondrous jumping, swinging and wrestling, I feared that I had perhaps made a reckless statement. After the lecture, I asked my grown daughter who was present, if I had done so. She said, "No, indeed. I am sure we should have gone for the walk."

It is assuredly true that the children are the best crop of the farm. Time, effort, energy, spent in keeping them interested in good things is the best kind of cultivation. I have often wished that I had money so that I could put the Youth's Companion into every home of the land. Next to our personal attention, nothing will help so much to lift the children from all that is mean and unseemly as good papers and books. These are now so cheap that no home need be without them. We have had many illustrations here at our college, that the boy or girl of good stuff need not even go without a college education. Energy, determination, vim, can even give this best of riches with no outside help at all. How much easier to secure the good book, the good paper, for the children.

CHILDREN IN THE CITY.

How many of our good friends live in the close quarters of the city, perhaps in a flat where a few feet of ground in front and back form the only exclusive places for the children. The children must have air and sunshine. Without these, pallor, weakness, disease, are sure to come. Left to the street, and all kinds of companionship will be theirs. Impudence, rudeness, often even the vilest vulgarity will be poured into their ears. Surely, no mother can contemplate this without a dread and horror that will do its utmost to bring invention to the rescue. I have a friend who has just this problem to solve. Her husband's business makes it almost impossible to escape the narrow limits of the city flat. The back yard is about 30x40 feet. This is boarded up so as to shut out the street children, and give the seclusion which is so imperative to the best good of the children. Lovely vines have converted the rude board fence into a thing of beauty. A hammock, screen to protect from the sun, pile of clean sand for the thousand and one things that the little architects will design, some clay to be used in moulding, blocks, brick, etc., all make that back yard a veritable paradise for the wee children. Other children in the neighborhood long to gain admittance to this little fairyland, and are themselves moulded into goodness as they know that the most perfect conduct is the only key that unlocks the door.

Thus this mother has not only solved the immediate problem for her own children, but she has a center of good influence which is throwing its wholesome beams all thru that section of the city. Whenever the busy mother can do so, she takes the children to the parks and there talks of birds, insects and even creeping things, for she learned to know and love these things when she was little, and she is handing these same bits of knowledge over to the eager children which have come to bless her home.

A friend at my side asks, "How about the coming years?"

This mother has thought this out, and has planned to live so economically and plan so well that as the children get older they can move into the suburbs, and there with garden, poultry and bees, the children may have that which will not only give them wholesome employment, but which will also interest them in the real, vital things of life, and thus prepare them for the sterner duties which will come in their later years. We see that this mother has devoted a great deal of time and thought that she may give her children an abundance of the good things, and keep from them anything that would poison character and vitiate the life. Ought we not all to do the same thing? Ought we not for our own good and also as a patriotic duty? Mr. Woodward, so well and favorably known in the State of New York, once told me that no man should be content to leave this world until he could leave behind children who were brighter and better than he. I believe he said truly. We can hardly hope to realize this happy experience unless we give earnest heed to this "best crop of the farm."

INFLUENCE OF GOOD EXAMPLE, TRUTHFULNESS AND HONESTY.

I believe the best cultivation that can be given this crop is that of wholesome example. How few of us that are parents are careful enough in this respect. Our words are not such as becometh the Gospel of Peace or our high position as parents. The rude slang, the profanity, the sarcasm, the thoughtless wit, all these should be kept away from the home circle. Ought we not to form an idea of just what we want this best crop to be? Then, ought we not with most earnest, prayerful effort strive to make our own lives conform to this ideal? The most blessed thing in character is absolute truthfulness. Are we careful enough that there shall be no lie in our lives? How quickly even the little deception will be detected by the child. If such deception beget in them a lack of genuine truthfulness, then we have sown the biggest tares in our best crop of the farm.

Next to truthfulness, honesty holds first rank. The child, the man, the citizen, are not what the home, the community, the country, stand in pressing need of unless transparent honesty glides the life. Who has not felt grieved to the quick as they have heard the father, perhaps about the tea-table, tell with great rejoicing how in some bargain or trade during the day he has cheated a stranger or neighbor to the tune of many dollars? Oh, that he could know what a black eye he was giving to the forming character of the child as he tells of any such experience as that given above.

KEEPING LITTLE HANDS BUSY.

I think one of the most helpful things in the best development of this "best crop of the farm" is the keeping of the little hands busy. This is one of the things which glorifies farm life. How difficult always to furnish the city boy with wholesome employment. On the farm it is not difficult at all. If we give the boy the bees, the chickens or the calf, which he is to care for, we will make this labor at the same time recreation. I know of a father who incited such interest in bees and chickens in his children that they were not only both of them induced to become great readers and students, but they were led into habits of industry and were each enabled to make money, independent of the father, enough largely to defray their expenses in getting a college education. When I was a boy, my father always kept me at work. While I was rarely ever late at school, I never got there much before the opening hour, and tarried afterwards at my peril. I thought then, at times at least, that my lot was a hard one. How many times since have I blessed my good father's memory as I have learned to appreciate his wisdom, and have seen its fruits in my own life.

The parent who succeeds in developing habits of industry and a love of good, honest work in the child, has certainly worked in the very best way to secure the best fruitage in the best crop of the farm.

ITALIAN BEES AND QUEENS

Having been 28 years rearing Queens for the trade on the best known plans, I will continue to rear the best.

Bees Wintered Poorly.

Bees have wintered poorly in this locality. I don't believe the working force will exceed one-half of what it was last year. The careless bee-keepers have lost heavily, and some have nothing left but empty hives and experience. One of my apiaries which contained 11 colonies last fall has been reduced to 5, on account of insufficient stores and cold cellar. The bees in my other two apiaries wintered well, the loss being only 3 colonies out of 241, and all are apparently in good condition. A. G. WILSON.

Vernon Co., Wis., April 12.

Prospects for a Good Fruit-Bloom.

Spring in this locality is late, wet and cold, but there will be an unusually good fruit-bloom, and the ground is being covered with a carpet of white clover, so we are hoping for a good season. JOHN W. BEATTY.

Clay Co., Mo., April 13.

Winter Losses.

The past winter was a hard one on bees in this vicinity. I put 12 colonies into winter quarters, and 11 of them came thru all right, but they will require a great deal of feeding. One bee-keeper here had 30 colonies last fall, and has lost 14 of them so far. I think he will make a successful bee-keeper, for to work with them is his "meat and drink."

Jerriso WILSON.

Watauga Co., N. C., April 3.

Bees Will "Ring Him Up" When Swarming.

I have a plan in my mind whereby I believe I can make the bees "ring me up" when a swarm issues. I shall work on the theory that when a swarm issues they pour out of

the hive with such a rush that a number of them accumulate in front of the hive on the ground or on the alighting-board.

I would like to ask the following questions of just as many bee-keepers as will answer thru the "Old Reliable," and when the answers are published I will give my plan with some photographs in this Journal.

1. When a swarm issues do the bees pour out of the hive with such a rush that they can not take to their wings fast enough, and consequently pile up in front of the hive to the amount of a half pound or more?

2. When a prime swarm issues, is the queen one of the last to come out of the hive?

A. B. GINXER.

Hardin Co., Iowa, April 13.

Handy Little Apiarian Tools.

I enclose a drawing of a little tool that I made for fastening "starters" in sections. The cut is about two-fifths of the full size, and will do the work as fast as any tool I know of. I use two of them, keeping one in a dish of hot water on a small kerosene stove, changing when one gets too cool. There is no wasting of foundation by melting, as with most of the high-priced, patented affairs. I made mine out of a broken saw blade, but a piece of heavy tin doubled, with the ends

toward the handle, will answer every purpose. The point should be rounded, not sharp, to avoid cutting the foundation in two.

I also have a small scraper for scraping propolis from sections, supers, etc., made in the same way, of steel, only the point is turned down and kept sharp. This beats the Golden section-cleaver out of sight. I use it to clean the tops of the sections before removing them from the super, and can do the whole 24 in the time it used to take me to do one with the Golden method.

Reading an article in the Bee Journal some time ago, suggesting that bee-keepers tell each other of any little thing they think might be helpful, is what prompted me to submit the above mites.

Mitchell Co., Iowa.

A. F. FOOTE.

Pickled Brood—Introducing Queens.

Pickled brood, in this locality, is of little moment. Colonies of Italian bees are not troubled with it. I have cured many cases among blacks and hybrids, simply by introducing an Italian queen. When her bees predominate the disease disappears. I am quite sure that pickled brood is not a starvation disease, as newly-bred swarms, gathering honey and pollen freely, have shown it in their first brood.

I successfully introduced over 50 queens, both home-bred and from a distance, to colonies in almost every possible condition, during the season of 1900. I used the Miller cage, pasteboard tacket over the candy. The pasteboard must be a little narrower than the hole

BINGHAM SMOKER.

DEAR SIR:—Inclosed find \$17.75. Please send our best smoke engine. I have one already. It is the best smoker I ever used.

Truly yours,
HENRY SCHMIDT, Hutto, Tex.

MADE TO ORDER.

BINGHAM BRASS SMOKERS!

Made of sheet brass, which does not rust or burn out; should last a lifetime. You need one, but they cost 25 cts. more than tin of the same size. The little open cut shows our brass hinge put on the 3 larger sizes. No wonder Bingham's 4-inch smoker engine goes without puffing, and does not drop ink drops. The perforated steel fire-gate has 381 holes to air the fuel and support the fire.

Heavy tin smoke engine, 4-inch stove, per mail, \$1.50; 3½-inch, \$1.00; 3-inch, \$0.60; 2½-inch, 40c; 2-inch, 35c. Bingham smokers are the originals, and have all the improvements, and have been the standard of excellence for 22 years. Only 3 larger ones brass.

BIRMINGHAM, WIS., April 10, 1901.

DEAR SIR:—Please send per mail one 3½-inch brass smoker. A decade's experience has convinced me that the Bingham is the best. Respectfully, M. P. CARV.

The Leader for 25 Years.

Bingham invented and patented all the real improvements made in Bee-Smokers and Uncapping-Knives in the last 25 years, and has introduced all the different sizes now advertised. Every bee-keeper having a smoker that will not go out is indebted to Bingham for its invention. If you buy a Bingham Smoker or Uncapping-Knife you are sure to get the best, and show that you appreciate valuable inventions. We make different sizes to suit all. No one has ever written or said that our 4-inch Engine is too large, but many of the best bee-keepers think it perfect.

T. F. BINGHAM, Farwell, Mich.

Please mention Bee Journal when writing.

which it covers. The thin shipping-tags used by express companies are made of just the right kind of pasteboard for this purpose.

After several years' experience with the Doolittle and Pridgen methods of queen-rearing, I prefer the Doolittle plan. With a quill I can transfer just as small larvae as Mr. Pridgen can move, "baby, cradle, all," and no combs mutilated.

To keep up with the times, I have been measuring the tongues of bees from several of my colonies. The variation in length is surprising. The longest-tongued bees that I have yet measured are from the granddaughter of an "Ade" queen. Their tongues measure from .25 inch to .254 inch from the base of the sub-nutrient to the tip of the ligula. This colony built combs for me all last summer, brood was taken from them frequently, yet they gave a small surplus, and had more winter stores than any other colony in my home yard.

The members of South Dakota have experienced some of the advantages of co-operation. Supplies were purchased thru our State association. For many of our members the saving of supplies alone many times repaid the membership fee of one dollar.

Perhaps for those who will use quilts on hives nothing is so good as Dr. Miller's quilts with several layers of newspapers between, says one of my neighbors who has used many of them.

Bees have wintered perfectly, both indoors and outdoors. E. F. ATWATER.
Yankton Co., S. D., March 1.

Report from Southern Georgia.

I began bee-keeping in 1897 with 5 colonies, and have made a great many mistakes, as most beginners do. I now have a small apary of 27 colonies which I run entirely for comb honey, as I find a better demand for it in my local market than for the extracted honey.

I live in southern Georgia, where we have no severe winters, and my bees are left on the summer stands in single-walled hives the year around, without the loss of a single colony in wintering.

I lived a swarm April 5th that weighed 15 pounds, and have put some supers on. Our main honey-flow begins about May 1st, and lasts until about July 1st. I take off the supers about July 15th, and let them build up for winter. I lose two or three colonies every spring from spring dwindling.

There is no army within 8 miles of mine. I like bee-keeping, and think that like the American Bee Journal, and think that no bee-keeper ought to try to get along without it.

H. T. HANNA.

Decatur Co., Ga., April 13.

Successful Cellar-Wintering.

Our bees came out booming this spring. From 400 colonies placed in the cellar last fall we have lost only 40 colonies, so I think we will have some bee-business this season. Our imported queens wintered very well, and came out with plenty of brood in their hives. Many of the bee-keepers in this section report heavy losses. We attribute our success in wintering to the bees having plenty of good food, good cellars, and last, but not less important, good, young, prolific queens.

APA L. PICKARD.
Richland Co., Wis., April 17.

Rendering Beeswax.

Having seen and read a good many articles in the American Bee Journal about rendering wax from old brood-combs, and about its being such an awful job, perhaps I can help some of those who think it so, by giving my plan. I think the solar wax-extractor is a slow process unless one has but a few colonies. I have tried a number of different waxes, and I think the following is "king of all," both for rapid work and ease.

I have made what I call a "sack press." It is 10x16 inches, inside measure, the posts and beams are 1x6 inch, the bottom is made of 3-inch planks, and the ends and sides are made of one-inch pine with one-inch slats left on

QUEENS!

Improved Golden and Leather-colored Italians are what H. G. QUIRIN rears.

We have one of Root's best long-tongued Red-Clover Breeders from their \$20 queen, and a Golden Breeder from Doolittle, who says if there is a BREEDER of golden bees in the U. S. worth \$50, this one is worth that sum. The above breeders have been added to our already improved strain of queens for the coming season. J. L. Gandy, of Humboldt, Nehr, wrote us on April 2nd last, saying that the colony having one of our queens had already stored over 400 pounds of honey (mostly comb); he states that he is certain that our bees work on Red Clover, as they were the only kind in his locality and apary.

A. I. Root's folks say that our queens are extra fine, while the editor of the American Bee Journal tells us that he has good reports from our queens from time to time. We have files upon files of unsolicited testimonials.

After considering the above evidence, need you wonder why our orders have increased each year? Give us a trial order and be pleased. We have years of experience in mailing and rearing queens. Safe delivery will be guaranteed, and instructions for introducing sent with each lot of queens.

each side of the bottom, these being covered with wire cloth so that the wax can pass thru. I also use a sack made of burlap with square bottom the size of the inside of the press. I have another plank to fit loosely in the press, which I set the back on. I use a sack with 2x10 inch screw. Set the whole thing on a large tub or trough with some water in it, and I am ready for business.

I boil about 25 or 30 combs at a time in an old wash-boiler, having it as hot as I can make it. I have the sack in the press, all ready, and the boiling wax is into it, fold down the sack, lay on the loose plank, screw down the sack, and the work is done. I can press it as dry as pounce that comes from a cider-press. After having done all this I refill the boiler, and let the next lot get hot while I am pressing the first. If the press is made strong, and the work is done right, from 250 to 300 combs can be pressed in a day.

WM. HOSSEL.

Hunterdon Co., N. J., March 21.

Prospects for a Good Honey Crop.

I put 11 colonies into the cellar last fall, but they were not very strong, so I lost 4 of them. Last season was a very poor one for bees in this part of the State, but the prospects are for a good honey crop this year.

ALBERT GOETSCH.

Dodge Co., Wis., April 19.

How the "Robber-Bees" Were Quelled.

I had a little experience once with bees when I first commenced in the bee-business. I had read up on the subject of bee-keeping, and considered myself competent to care for and manage an apary. I soon started out in quest of bees, and purchased two colonies in box-hives. This was in early spring. I kept close watch to see that all was well with them, and everything went well the first day. The second day trouble came. One of my hives was full of honey and bees, the other one was light in both.

About 1 p.m. I noticed there was something wrong in the apary. I soon discovered just what the trouble was—they were robbing my best colony. I thought how very fortunate I was to have learned just how to manage a bad case of robbing like the one I now had to deal with.

I sent one member of the family after straw, another after water, and myself after the sprinkler. I soon had the front of the hive, which was being robbed, piled high with straw, and the sprinkler running full time. But what perplex me was, the bees kept piling into the hive, and none came out, but soon all was quiet. I had conquered them. I decided then and there that I was well informed in all the branches of bee-keeping. I didn't learn my mistake till the following day, when the bees again (as before) came out for their daily play-sport.

A. E. WILCOTT.

Hampshire Co., Mass.

Value of Honey as Food.

"Comparatively few to-day know the great value of honey both as a food and a medicine. Were its value as a medicine thoroughly known, it would displace in hundreds of families the domestic remedies or quack compounds now depended upon for their ailments." If every bee-keeper in the country would write a series of articles for his local weekly newspaper upon the value of honey for food and medicine, it would soon create a demand, to supply which would require a much larger quantity than is now produced.

Thus says a writer in one of our agricultural papers. While there may not be the claims made, all the writer thinks, yet in them is something worthy of thinking about. If honey is really the *good* thing we bee-keepers

Tennessee Queens!

Fine lot of Choice Tested Queens reared last season, daughters of select imported and select golden queens, reared 3/4 miles apart, and mated to select drones, \$1.50 each; untested warranted queens, from same breeders, either strain, 75c each. CAREER AND CHARACTER OF ABRAHAM LINCOLN.

An address by Joseph Choate, Ambassador to Great Britain, on the career and character of Abraham Lincoln his early life—his early struggles with the world—his character as a diplomat in the later years of his life and his administration, which placed his name so high on the world's roll of honor and fame, has been published by the Chicago, Milwaukee & St. Paul Railway, and may be had by sending six (6) cents in postage to F. A. Miller, General Passenger Agent, Chicago, Ill. 18A3t

think it is, are we doing right in not publishing the matter more? Are we not 'hiding our light under a bushel' the most of the time, when, by letting it shine brightly all the time, we might honor our calling by leading others to partake of the good which comes to the world thru that best of all sweets—honey? —G. M. DOOLITTLE, in the Progressive Bee-keeper.

Load a Worker-Bee Can Carry.

A Stray Strawn in Gleanings in Bee-Culture says: "A worker, according to Alex. Astor (Rev. Int.), can carry about an eighth more than its own weight when honey is given to it. The maximum load of nectar brought in he found to be (about June 1st) 65.5 milligrams (a little more than three-fourths its own weight); and from then to Aug. 3d the weightings showed 50 mg., 45, 40, 28, 25, 18, 10, 10." It appears, then, that a bee can carry more of honey than it can of nectar—not larger in bulk, but greater in weight. These figures are very interesting.—EDITOR.]

A Queen Between the Lips.

A pointer for those who, like myself, are forgetful: There is a queen I wish to remove. The hive is all open; I hold in my hands the frame she is on, but I have no cage! It is a long way back to the honey-house; the sun is hot, and robbers have found us. If I place the frame back into the hive in order to go and get the cage, I shall miss the queen; I can do nothing so long as this frame is in my hands. I want that queen! What shall I do? Simply place her, head in, carefully between the dry lips, close the hive, and then go and cage her. See?

I hold cells, root in, the same way, very often.—"SWARTHMORE," in the American Bee-keeper.

Good Apiarian Advice.

Produce what your market calls for: this will be both comb and extracted honey. Some customers will want comb, and some extracted—please both. Bottle nothing but first-class honey. Furnish this to the grocers around you to sell on commission, as many will sell in this way who would not purchase outright. Call all your wits into play and remember, it is as honorable to sell honey as to sell wheat or potatoes. Give good weight, and you will soon work up a good trade, and get retail prices for your goods.—F. P. CLARE, in the Bee-Keepers' Review.

Railroads Against Comb Honey.

Referring to the fact that the Grand Trunk railway in Canada has ruled out a class of honey as freight, and to the information given in a previous number of this journal as to contemplated action on this side, the editor of Gleanings in Bee-Culture expresses himself in the following vigorous style:

I regard this as a most serious matter. I can not think of anything that would handicap bee-keeping any more, unless it be foul or black brood, than to have the railroads practically refuse to handle comb honey. We can not afford at the present rate to send any quantity by express; and if the new freight-classification should go thru, we could not afford to send it by freight. Many large apiaries would be totally unable to dispose of their product, and the industry would not

only be crippled but almost annihilated. I have already laid the matter before General Manager Secor, of the National Bee-Keepers' Association. Action should be taken at once, it seems to me, because it is far easier, according to our experience, to prevent a bad classification getting on the tariff-books than to have such classification rescinded after it is once in force. Why, our Association could better expend every dollar in its treasury rather than have such a foolish, unreasonable, and unequalled discrimination against our industry. I am sure that our worthy general manager will take suitable action at once. In the meantime, the Ontario Bee-Keepers' Association in Canada should see what could be done to have that unjust ruling of the Grand Trunk railway rescinded. It is apparent that the proposed action on this side of the line was instigated by the fool ruling of the Grand Trunk on the other side; and as long as it stands thus, so long it will be a menace to us.

CONVENTION NOTICES.

Illinois.—The spring meeting of the eastern division of the Northern Illinois Bee-Keepers' Association will be held at the residence of B. Kennedy, 7 miles southeast of Rockford, Ill., on Rural Route No. 5, and 3 miles northeast of New Milford, Ill., Tuesday, May 2, 1901. All interested in bees are cordially invited to attend.
B. KENNEDY, Sec.

Connecticut.—The Connecticut Bee-Keepers' Association will hold its next meeting at New Haven, in the Aldermanic Chamber of the City Hall, on Church Street, Wednesday, May 8, 1901, at 10 a.m. Among the topics for discussion are these:

With how many colonies did you begin the winter? How many colonies have you now? To what were the losses due? Which do you prefer, black or Italian bees? How many

frames of honey do you allow a colony for winter? What about feeding syrup in paper bags? Have you tried keeping two queens in one colony? For the ordinary bee-keepers, are artificial or natural methods better? Do you ever have moldy combs? When did your bees take their first good flight this spring? What kind of feeders do you use? Do you prefer a large or small hive? When do you get the best honey crop?

Yo r presence is earnestly requested.
ELLEN E. PECK, Sec.

ALBINO QUEENS If you want the most prolific Queens—If you want the gentlest Bees—If you want the best honey-gatherers you ever saw—try my Albinos. Untested Queens in April, \$1.00; Tested, \$1.50, 11A26 J. D. GIVENS, LISBON, TEX.

A261 **Marshfield Manufacturing Co., Marshfield, Wis.**
Please mention Bee Journal when writing.

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen **FREE** as a Premium for sending us **TWO** new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us **FOUR** new subscribers with \$4.00.)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipt, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Apr. 18.—Choice grades of white comb honey sell at 16c, and there is no surplus in sight. Other grades of comb sell fairly well at the following prices: No. 1 grades of white, 14c@15c; off grades, 13c; light amber, 13c; dark amber, 10c@11c; buckwheat and other dark combs, 9c@10c; candied and mixt colors, 7c@9c. Extracted is dull, and prices very weak, with the exception of some Fancy and Golden and clover grades, which is quotable at 7c@8c; ambers, 6c@7c; dark and buckwheat, 5c@6c. Beeswax, 30c.
R. A. BURNETT & CO.

BUFFALO, Apr. 18.—Fancy white comb, 15c@16c; poor, dark, etc., 8c@13c, as to grade. Demand good on fancy. Beeswax, 20c@28c, as to grade.
BATTERSON & CO.

OMAHA, Apr. 25.—There has not been any change in the condition of the market since our prices during the last month, and we do not look for any change until new crop makes its appearance. There is not any more stock held in this part of the country that will be used up at the present range of prices. We quote fancy white comb, 15c@16c. Extracted, slow sale, 7c@8c for white.
PEYCKE BROS.

DETROIT, Apr. 18.—Fancy white comb, 14c@15c; No. 1, 13c@14c; dark and amber, 10c@12c. Extracted, white, 6c@7c; amber and dark, 5c@6c. Beeswax, 27c@28c.
M. H. HUNT & SON.

NEW YORK, March 19.—Our market is virtually bare of comb honey, and there is a fair demand for all grades. Fancy white is still selling readily at from 15c@16c; No. 1 white at from 13c@14c; amber at from 12c@13c; buckwheat, 10c@11c, according to quality and style of package. As to extracted, the market is quiet and inactive and a certain amount will have to be carried over again. Prices are declining somewhat, and if the honey is not moved in large lots, concessions will have to be made. We quote: California white, 7c@7½c; light amber, 6½c@7c; other grades and Southern, 6c@7c per gallon. Beeswax very firm at 28c@28½c, and for exceptionally fine yellow, 29c.

BILDBRETH & SEGELKEN.

CINCINNATI, Apr. 18.—The demand for comb honey is nearly over. The stock of it also well cleaned up. Fancy white brings 10 cents. Extracted is in fair demand; dark sells for 5½c; better grades bring 6c@7½c; fancy white clover from 5½c@6c.
C. H. W. WEBER.

KANSAS CITY, Apr. 18.—There is very little honey offered, and the demand is steady, selling from \$3.50@3.90 per case, fancy white, no amber on the market at this time. Extracted, no change; white, from 8c@9c; amber, there is a little on this market that could be sold from 7½c@8½c. Beeswax scarce and demand good, at 25c@26c.
W. R. CROMWELL PRODUCE CO.
Successors to C. C. Clemens & Co.

ALBANY, N.Y., Apr. 19.—Honey market quiet. Light supply and light demand now. The stock is well cleaned out, so will be no old honey to carry over this season.
H. R. WRIGHT.

BOSTON, April 4.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15c@16c, with a fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8c@8½c; light amber, 7½c@8c. Beeswax, 27c.
BLAKE, SCOTT & LEE.

SAN FRANCISCO, April 3.—White comb 12c@13c; amber, 9c@11c; dark, 6c@8c cents. Extracted, white, 6c@6½c; light amber, 4½c@5c; amber, 4c@4½c. Beeswax, 26c@27c.

Despite general expectations and contrary to experience of previous years, new honey is reported on market. For some new amber extracted from Ventura country 6 cents is asked, but this is above the views of buyers. Old is still offering in moderate quantity, both comb and extracted, mostly amber.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

\$15.00 and \$25.00 Queens

Having a Measured Tongue Reach.

The call for queens of our celebrated \$200 imported mother has been so great that we have decided, in addition to the \$2.00, \$4.00, and \$6.00 grades of this stock, to offer some \$10.00, \$15.00, and even \$25.00 of this same blood. But these prices are for tested queens, the tongues of whose bees have been measured.

The \$10.00 queen is guaranteed to produce bees with a tongue-measurement of 19-100.

The \$15.00 queen, 20-100.

The \$25.00 queen, 21-100.

These last are very rare and with one exception this (21-100) is the longest tongue reach yet secured. We reserve the right, when we do not have the stock with the tongue reach called for, either to return the money or to send the next lower, remitting the balance. It would be well for our friends to put in their orders at once, and as soon as we get the grades we will send notice. When the money is sent, the queens will be forwarded. These will be put up in the very best manner possible; and while we guarantee safe arrival in good order to any point in the United States, on any railway line, we will not guarantee safe introduction. Such valuable queens should be released on hatching brood.

N. B.—It seems as if it ought not to be necessary to say that no one but a queen-breeder or a large honey-producer should order these high-priced queens; but it is a fact according to our experience that beginners with only a few colonies will order our highest priced imported queens. Such bee-keepers have no more use for such queens than a pig has for a wheel-barrow.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale. The picture shown herewith is a reproduction of a motto-queen-button that we are furnishing to bee-keepers. It has a pin on the back to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

FEMININE FLOCK is exhibited by Miss Rose Kembleott, who, in the good State of Colorado, has worked up in 12 years from 5 colonies to nearly 200 colonies, with only the textbooks, bee-keepers, and her own experience to guide her. May her success continue.

MR. F. GENT, of Wright Co., Minn., who has been offering bees for sale in our advertising columns, wrote us April 30th, when re-ordering his advertisement: "The American Bee Journal is a good puller." Of course it is. If you have any good thing to sell that bee-keepers want or need, offer it thru our advertising columns.

MR. N. E. FRANCE, of Grant Co., Wis., writing us April 27th, says:

"Prospects are for a good honey crop in Wisconsin this season. But some lost many colonies of bees during the winter. 'I am pleased to know that Michigan now has a law to suppress foul brood. I have visited many times that every State had the same, then the disease could be eradicated with no importing or sending of diseased bees from one State to another.'"

THREE FRIENDLY EDITORS are shown on the first page this week. The engraving appeared first in the Bee-Keepers' Review for March. Mr. Hutchinson had the following to say, in part, concerning those represented in the picture:

It is a fortunate fact for the readers of three of the leading bee-journals, that the editors are really and truly friends. Instead of wasting their time and energies, and using up space in their journals, in "spats," they all pull together for the good of the pursuit to which their journals are devoted.

When the Wisconsin bee-keepers last met at Madison, these three editors met by appointment at the Chicago Milwaukee & St. Paul station in Chicago, went together to Madison, and whiled away the time on the way by discussing bee-journalism—each trying to learn from the experience of the others how he might improve his own journal.

E. R. ROOT was called home from Oberlin College, some 15 or 20 years ago, to help his overburdened father; and, gradually, he went into the editorial jammer, until, at last, he was "given head," not only in dealings, but in the revisions of the "ABC" book. Mr. Root has had exceptionally good advantages for becoming a first-class bee-keeping editor. He was brought up with the bees, and in connection with the largest factory there is devoted to the manufacture of bee-supplies. If I were to tout out his leading characteristic, or, at least, the one that has had a great deal to do with the building up of Gleanings, I should say that it was his alibi—the faculty of making and keeping friends. An editor has many times to disagree with his correspondents, but Mr. Root seems to be able to do this without giving offense. There is a great difference between telling a man that he is a liar, and explaining to him where he has made a mistake. Mr. Root takes the latter course.

About the time that Bro. Root began working on Gleanings, I found George W. York at work for Mr. Thomas G. Newman on the American Bee Journal. After working several years for Mr. Newman, Mr. York had the "nerve" to buy the American Bee Journal. Only a publisher knows what excellent business management there must be to furnish such a paper as the Ameri-

can Bee Journal at \$1.00 a year, but Bro. York has shown himself equal to the emergency. He has imbibed that Chicago spirit of push and enterprise that succeeds where common words fail. If I could but print out Bro. York's leading characteristic, I should say it was exactness, or correctness. That disposition that leads one to say, "first be sure you are right." And, having decided that he is right, Bro. York sticks to it.

Working so long on a bee-journal, attending so many conventions, reading so much bee-literature, etc., have enabled Bro. York to become pretty well posted upon things apianian; and he succeeds in making a most valuable journal—one that would be mist, and sadly mist, were it to drop out of the ranks.

When it comes to writing of myself the pencil halts. I have written in the Review so much about myself that I begin to fear that it may be proving tiresome; but I would like to say this, that of late I am becoming more imbued with the spirit of trying to help bee-keepers, to be of some real and lasting benefit to them; to arouse, encourage and inspire them; to set them to thinking; to lift them out of ruts, and to lead them to see in their business as a business. It is all right to tell a man exactly how to perform a certain piece of work, but sometimes it is of more benefit to rouse him, and set him to thinking out problems for himself.

We have no comment to add to the foregoing, except to say that we are pleased to present to our readers the portraits of our two "fellow-sufferers."

THE MAY LADIES' HOME JOURNAL.—Some of the many excellent features of the May Ladies' Home Journal are: "The Brilliant Social Reign of Harriet Lane," "When John C. Calhoun Went a-Wooling," "When the Animals Escape from the Zoo," "Some Recent Medical Cases of Double Personality," "My First Colony of Bees," and Clara Morris' "Frank Sen," the romance of a little Japanese girl abroad. To those arranging for a summer holiday Edward Bok offers some pertinent suggestions, and the methods of "Preserving a Husband in Summer," and "Keeping Summer Boarders with Success," are dramatically detailed. The admirable pictorial features include a page drawing, "President Lincoln's Call for Volunteers," by W. L. Taylor; "In the Fold," the first prize picture of the 27,000 photographs submitted in the Journal's recent contest; a page of Miss Gertrude Kaschier's photographs—the first of the "Four Women Photographers of America" series—and two pages giving "A Glimpse of Picturesque Canada." There are three architectural articles, and seasonable contributions on gardens, flowers, lawns, cooking, and needle-work. There are also four pages from the Journal's fashion writers and artists. By The Curtis Publishing Company, Philadelphia, Pa. One dollar a year; ten cents a copy.

SOMNAMBULIST for several years has been one of the most interesting and helpful contributors to the Progressive Bee-keeper—often being referred to as a "dreamer." "Wandering sleep-head" would hardly be appropriate. A Stray Straw in Gleanings in Bee-Culture reads thus:

Somnambulist thinks that bee-keepers too often say "I" when they should say "we," thus giving due credit for the help of faithful wives. Amen, say I. Also that wives, like queens, should be chosen, not for beauty, but for real worth. Now, here's what puzzles me: One who places such high estimate upon the value of wives, and shows such discriminating judgment regarding them, would surely be expected to have a wife of the best type; and yet, if I am rightly informed, Somnambulist, who is no longer a spring chicken, has never had a wife.

If we are "rightly informed," we can't imagine what "Sonny" would do with a wife.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., MAY 9, 1901.

No. 19.

Editorial.

Strenuous Queen-Rearing is the subject written on by Mr. J. H. Martin, as will be seen by the report of the California convention in this number. The paper treats upon a new phase in queen breeding and distribution. We understand that the plan was almost unanimously endorsed by those present at the meeting. Mr. McIntyre made an estimate that if a bee-keeper could definitely depend upon supplying a large number of bee-keepers with queens, and without advertising and the uncertainties of the present method, that queens could be reared for 15 cents each. The members present were willing to pay 25 cents each, and upon that basis the few present were ready to place an order for 1,000 queens. Upon this basis Mr. McIntyre would probably receive orders in his own county, and in Los Angeles county, for over 5,000 queens; but not being prepared for such extensive queen-rearing just at present, the matter is under advisement, meanwhile others are thinking of entering the field and working upon this plan.

Now the questions before the fraternity, or rather before the queen-breeders, are, Can good queens, such as Mr. Martin's paper calls for, be bred for 25 cents each? Can a queen-breeder rear from 5,000 to 10,000 good queens per year? Or, Mr. Queen-Breeder, how much will you charge per month for your services while rearing queens for from 50 to 100 bee-keepers?

The object in adding the foregoing is that a thoughtful discussion of the matter may be brought out. Mr. Martin thinks his plan is the right one for improving the working qualities of a large number of colonies of bees.

Are Old Combs Objectionable?—It is a fact that fashion seems to have at least a little to do with practices of bee-keepers in different parts of the world. In this country it is the fashion to continue to use brood-combs when many years old, while in other countries they are considered objectionable when ten, five, and in some places three years old. The rejection of old brood-combs comes from the belief that the cocoons left by successive generations of young bees make the cells so small that bees reared in them can not attain their full size. A few in this country have said that they found bees reared from old combs were a third smaller than others, but others say they can see no difference when the combs are 20 years old or older. One writer in *Gleanings in Bee-Culture*

argued that bees must necessarily be smaller because the cocoons left from year to year do not leave room for full development. But if that proves anything it proves too much. Old combs may be found in which the septum measures $\frac{1}{4}$ of an inch, and it was shown in *Gleanings in Bee-Culture* that if the amount of cocoons left on the cell-walls was the same as at the bottom, the inner diameter of such cells would be so reduced that instead of measuring $\frac{5}{8}$ to the inch it would take 13 of them, and it would take $\frac{6}{11}$ of the bees reared in them to weigh as much as an ordinary worker. No one pretends that such dwarfing ever takes place.

Some worker-comb 25 years old was measured by E. R. Root, and he found that while the septum was $\frac{1}{4}$ of an inch thick the cell-walls were not materially thickened. It seems that while the bees leave the bottoms of the cells undisturbed they continually remove the cocoons from the side-walls, so that by drawing out the cell-walls a little the cell is made as large as ever. From this drawing out of the cell-wall it happens that very old comb measures an inch in thickness, while comb newly built measures only $\frac{3}{4}$ inch.

Another item that should not be disregarded is the preference of the bees themselves. Give them their choice between an old black comb 20 years old, and a fresh comb in which little or no brood has ever been reared, and they will promptly choose the old comb, whether it be for the rearing of brood or the storing of honey. It is also claimed that bees winter better on old than on new combs.

Honey-Adulteration in Illinois.—From the First Annual Report of the State Food Commissioner of Illinois—1899-1900—we take the following as written by State Analyst E. N. Eaton last December, which bears directly on this subject.

HONEY.

Pure honey may be defined as the nectar of flowers, transformed, and stored in the comb by the honey-bee. Extracted or strained honey is the same article removed from the comb by man, usually by centrififugal force. Comb honey can only be adulterated by the bee which seems to have a patent on capping the cells. Extracted honey, next to vinegar, is more universally adulterated than any other staple food products.

In Minnesota, before the honey clause was added to the Food Statute, about 35 per cent of extracted honey proved to be adulterated. In Illinois about the same ratio of adulteration was proven to exist. Last year a committee acting for the National Bee-Keepers' Association, secured a large number of samples in Chicago. Being at the time employed in commercial work, I examined the samples for the Association, and found that more than 50 per cent were adulterated. The present month finds extracted honey again seeking the winter trade. Inspector Mrs. Frank

Hubbard has visited many stores in Chicago, and reports very much less extracted honey offered than the year before. This is owing to the enforcement of State law requiring the labeling of adulterated honey, thus driving a dishonest competitor from the market. While none of the samples taken this winter have as yet been analyzed, many of them are of those brands which proved genuine in former analyses.

The most common adulterant of honey is glucose, altho adulteration with cane-sugar and invert sugar is possible and sometimes practiced. The adulteration thus far discovered on the Illinois market has been of the cheapest and most gross kind—glucose flavored with a small slice of honey in comb.

The Illinois Food Commission is doing a good work for everybody in this State. There are still some weaknesses in the present law under which the Commission are working, which, when removed, will tend to make their efforts still more effective in the future. We hope the strengthening amendments will be approved during the present session of the State legislature at Springfield.

A Woman With 500 Colonies.—*Gleanings in Bee-Culture* has a report from Lydia Crawford Harris, who last year from an apiary of 166 colonies obtained 160 40-pound cans of extracted honey, and 171 cases of comb honey. She also has two other apiaries—in all 500 colonies. If something is not done to stop this sort of thing there is no telling to what it will lead. Instead of being the down-trodden, submissive creature that a properly constructed woman is expected to be, Mrs. Harris boldly declares her independence of the "lords of creation" by saying:

"As we women in Colorado enjoy all the rights of voting, from the lowest county officers to the President of the United States, I propose to operate these yards with women help."

As a comment on the above, Editor E. R. Root adds this:

"If the right of franchise has this effect on the gentler sex, let's give the women a chance. If the women of the land could vote there would be less of jobbery and wickedness in high places. I'll risk the women, every time."

A Smoker With Double Bellows has been shown in *Gleanings in Bee-Culture* which operates so that a puff is given as usual at the pressing together of thumb and fingers, and another puff as they separate; but the two puffs give no more smoke than a single puff of the ordinary smoker. A stray straw suggests that a smoker could be made to give a perfectly continuous blast by having bellows after the fashion of a melodeon, allowing no possible sucking of smoke into the bellows, but there would be a loss in the strength of the blast.

Convention Proceedings.

Report of the California Convention.

The 11th annual convention of the California State Bee-Keepers' Association was held in Los Angeles, Feb. 25 and 26, 1901. There was a small attendance, but all were hopeful, and were preparing for a good honey harvest.

Secretary McIntyre explained some of the advantages of the new State Law in the interest of bee-keeping, thru the efforts of Assemblyman R. M. Clark, of Ventura, assisted by other southern legislators. The new law reads as follows:

AN ACT

To promote the Apicultural Interests of the State of California by providing County Inspectors of Apiaries, and defining their duties, and providing for their compensation, and repealing the act entitled, "An Act to authorize the Board of Supervisors of the several counties of this State to appoint Inspectors of Apiaries, and provide for their compensation, and defining their duties, and for the further protection of Bee-Culture." Approved March 13, 1898.

THE PEOPLE OF THE STATE OF CALIFORNIA, represented in Senate and Assembly, do enact as follows:

SECTION 1. Whenever a petition is presented to the Board of Supervisors of any county, signed by ten or more persons, each of whom is a property-holder resident of the county, and possessor of an apiary, or place where bees are kept, stating that certain or all apiaries within the county are infected with the disease known as "foul brood," or any other disease which is infectious or contagious in its nature, and injurious to the bees, their eggs, or larvae, and praying that an inspector be appointed by them, whose duty it shall be to supervise the treatment of said bees and apiaries as herein provided, the Board of Supervisors shall, within twenty days thereafter, appoint a suitable person, who shall be a skilled bee-keeper, Inspector of Apiaries. Upon petition of ten persons, each of whom is a resident property-holder, and possessor of an apiary, the Board of Supervisors may remove said inspector for cause, after a hearing of the petition.

SECTION 2. It shall be the duty of the Inspector in each county to cause an inspection to be made, when he deems it necessary, of any or every apiary, or other place within his jurisdiction in which bees are kept; and if found infected with foul brood, or any other infectious or contagious disease injurious to the bees, or their eggs or larvae, he shall notify the owner or owners, person or persons, in charge, or in possession of said apiaries, where bees are kept, that the same are infected with foul brood, or any other disease infectious, or contagious in its nature, and injurious to bees, their eggs, or larvae; and he shall require such person or persons to eradicate and remove such disease or cause of contagion within a certain time to be specified. Said notice may be served upon the person or persons, or either of them, owning or having charge, or having possession of such infected apiaries, or places where bees are kept, by any Inspector, or by any person designated by the said Inspector for that purpose, or they may be served in the same manner as a summons in a civil action. Any and all such apiaries, or places where bees are kept, found infected with foul brood, or any other infectious or contagious disease, are hereby adjudged and declared to be a public nuisance; and whenever any such nuisance shall exist at any place within his jurisdiction, or on the property of any non-resident, or on any property the owner or owners of which can not be found by the Inspector after diligent search, within the county, or upon the property of any owner or owners upon whom notice aforesaid has been served, and who shall refuse or neglect to abate the same within the time specified, it shall be the duty of the Inspector to abate the same, either by treating the disease, or by destroying the infected hives, together with their combs and bees therein.

The expense thereof shall be a county charge, and the Board of Supervisors shall allow and pay the same out of the general fund of the county.

SECTION 3. It shall be the duty of the County Inspector of Apiaries to keep a record of his official acts and doings, and make a monthly report thereof to the Board of Supervisors; and the Board of Supervisors may withhold warrants for salary of said Inspector until such time as said report is made.

SECTION 4. The salary of the County Inspector of Apiaries shall be three dollars per day when actually engaged in the performance of his duties.

SECTION 5. An Act entitled, "An Act to authorize the Board of Supervisors of the several counties of this State to appoint Inspectors of Apiaries, and provide for their compensation, and defining their duties, and for the further protection of Bee-Culture," approved March 13, 1898, is hereby repealed.

SECTION 6. This act shall take effect and be in force from and after its passage.

JOINED NATIONAL ASSOCIATION.

J. H. Martin then brought up the question of the advisability of the members of the State Association joining the National Association, and after a discussion of the proper method of taking this admittedly wise act, it was

agreed that the Association join the National organization as a whole.

ADULTERATION OF HONEY.

G. S. Stubblefield spoke of the prevailing flagrant adulteration of honey, and urged that steps be taken to fight the evil. He said he knew of two or three parties who are handling adulterated goods, and remark that no matter how dry the year, there always seemed to be plenty of goods on the market. The stuff is concocted in syrup factories, from glucose, he said. He thought there ought to be a committee appointed to investigate the matter. The State law covered the evil, but was not enforced. The district attorney had promised to take up any case of honey adulteration brought before him.

Secretary McIntyre suggested that every member of the Association consider himself a committee of one, authorized to investigate honey adulteration in their respective districts.

ELECTION OF OFFICERS.

At the time of the election of officers the following were chosen to serve the coming year: President, G. S. Stubblefield; vice-presidents, H. E. Wilder, G. W. Brodbeck, Robert Wilkin, E. A. Roney, and T. R. Canady; secretary and treasurer, J. R. McIntyre, Sespe; executive board, J. H. Martin, E. Hart and G. W. Brodbeck.

A general discussion of the affairs of the bee-keepers' exchange which has frequently lapsed and languished in late years, followed; but while the necessity for an exchange was admitted, no tangible results came of the arguments.

President Wilkin gave an interesting talk on the progress of bee-keeping during his forty years' experience, recounting the many mechanical improvements that have been made, and emphasizing the need of co-operation among apiarists.

CONDITIONS IN LOS ANGELES COUNTY.

President Brodbeck, of the Los Angeles County Bee-Keepers' Association, stated after the close of the session that conditions in Los Angeles county were favorable on account of the rains, but that the continued drought had greatly decreased the number of colonies. Four years ago the estimated production was 4,000,000 pounds. Since then 75 percent of the bees have died. This season, however, is so far much more favorable than the season four years ago, and therefore there may be a very fair yield, notwithstanding the decrease in colonies. Most of the apiaries in this county are situated along the lower mountain sides, from San Fernando to the eastern county line, and in the hills around San Pedro.

T. O. Andrews, of Orange county, described the state of the honey-business along the Santa Ana river, where he has owned several apiaries. Seven years ago he took 18 tons from 325 colonies, distributed in four apiaries. Later on, when there was a good flow, he took 27 tons. That year he could grasp with one hand seven kinds of growing wild flowers, but now there is nothing blooming but alfalfa, and even that was not good for honey purposes last year. He had lost heavily, his stock dwindling to 150 colonies. He was hopeful for the near future, however.

Mr. J. H. Martin read the following paper on,

Strenuous Queen-Rearing.

In these twentieth-century days we hear much about strenuous living and working. I suppose strenuous is only another term for high-pressure, and we have had high-pressure farming, high-pressure poultry rearing, high-pressure commercialism, and high-pressure many other things; but I have never heard much of high-pressure bee-keeping.

High-pressure is, however, too much out of date to apply to twentieth-century bee-keeping, and "strenuous" is the term; and I have an idea that to commence at the root of the matter, we need a more strenuous queen-rearing.

Let us consider the subject. During the past season I found a strain of bees in the apiaries I was managing that were so far superior to the rest that, had the bees all been bred from the queen of that colony, our honey crop would have been increased by several tons.

The discovery that this strain were such good rustlers for honey was not made until the season was well advanced; and now, in order to get the full benefit from that strain, it must be gradually diffused thru the whole apiary.

When I find a strain of bees like those mentioned I am impatient to get the whole apiary up to that standard, and the need of queens when I want them, and the lack of time to rear them when my energies are devoted to the extractor or at other work. In fact, I am strenuous at something else, and need an extra-strenuous plan to supply the queens.

I think every bee-keeper present has observed that not one apiary in a hundred is properly queened, and I think we all have a dim sus

panion that our own apiaries are not up to the standard we desire. We hear of golden yellow queens, leather color, long tongues, and even \$100 queens. To make a good start we should like one of those \$100 queens; but after considering the lank condition of our purse we finally conclude to send for a dollar queen, and that is about as far as we get this year; but next year, if we have a big crop of honey, we will do better. Our dollar queen may be good, bad, or indifferent; and, whichever it is, we do not get much out of her.

Then you know that queen-rearing has become a great science of late years. Alley's plan used to be good enough for me; but now it is dipping sticks, two by two, transfer of royal jelly, transfer of larvae, and puttering until your head swims. Oh, it is so strenuous!

But I see light at last. When I read Pridden's plan of making queen-cells by the peck, and queens by the quart, a great load seemed to be lifted from my mind, and I formulated the following more strenuous plans for queen-rearing:

In the first place, every bee-keeper needs the very best queens that can be reared—best in hardiness, prolificness, and notably in the honey-gathering qualities of her progeny.

In the second place, there are but few bee-keepers who have the combination of qualities that will insure their success in modern strenuous scientific queen-rearing. Now, my plan is that a certain number of bee-keepers in a given locality turn their queen-rearing over to an expert in that line of work. A contribution from each bee-keeper interested would enable the expert to commence operations with the best available stock. Each bee-keeper in this district should agree to take a certain number of queens per annum; and, having a definite number of queens to rear, and a large number of them, the expert could rear them at a minimum cost to the bee-keeper, and at the same time with a good profit to himself.

A person devoting his entire attention to queen-rearing will strive to improve his stock, and his patrons will receive the full benefit, or the patrons in this case would have an influence in keeping the stock up to an approved grade.

Our usual plan is to send for a breeding-queen and rear daughters, granddaughters, and great-granddaughters from her, and trust to a promiscuous mating with our drones.

Our expert could be so located as to control the mating of queens with selected drones, and the bee-keepers in this district would get queens only one removal from the original, or daughters, and from the very best stock in the country. In our present haphazard way we dilute the blood too much by the many removes from the original stock, and this would be entirely avoided thru our expert queen-rearing station.

This plan is in line with the division of labor which at present is recognized as the most effective way for accomplishing great results; and the question is, Are the bee-keepers ready for this advance in their methods of management?

I will leave the question to you for solution, believing that, if it is put into practice, the honey-producing power of our apiaries will be advanced many fold.

Long-Tongued Bees—Fad or Fallacy, Which?

BY G. M. DOOLITTLE.

OF late years some of our bee-papers start off with some new idea, or some old one revived, and in a little while the heads in all beedom seem to get twisted out of the "straight and narrow path," and run off after an "apparent something," which, a few years later, is dropt as if it never had an existence, with hundreds and thousands of hard-earned dollars wasted over the hobby or fad.

The fad now "on" seems to be "long-tongued bees," the fad having run long enough, and the excitement become great enough to warrant asking \$10, \$15 and \$25 for queens, giving bees having a certain length of tongue-reach. And our good Editor York is compelled to fall into line with the announcement at the head of his advertisement, "Long-tongued bees are demanded now." Of course, the "fad" has caused the demand, and no one blames the editor for heading his advertisement in accord with that truth. But is the fad founded on truth, or on a fallacy? That is the question that should be asked in all seriousness, before more money is wasted on the fad.

Long-tongued bees are either better workers, or they are not better. Then, they may work on red clover where that abounds, and be a great advantage there, without being any more industrious at gathering honey from apple-bloom, basswood or buckwheat, the nectar from which any bee could reach having a tongue not more than half as long as the shortest tongues measured. That being the case, long-tongued bees would be an advantage only to those residing where red clover and other long-tubed flowers abound. This brings me to look into this part of the mat-

ter, for red clover has not blossomed to any extent in this locality for the past 15 years, owing to a "midge" or very small larva which works in the head just before it would blossom, thus reducing what used to be fields "red with clover blossoms" to fields having a dull-brown color, which is assumed at blossoming time from the workings of this pest in central New York. So, if these long-tongued bees are not better otherwise, their working on red clover is of no advantage to me. So I turn to the testimony:

On page 220 of March 15th Gleanings in Bee-Culture, I find these words:

"The movement for longer tongues is simply to get the red-clover crop of the North, which now is practically all wasted. The bees *NO ONE CLAIMS would be any better except on that account.*"

The italics are mine in the above quotation, and were put there to draw attention to the words, as they point to a fallacy somewhere. If the above is correct, then these long-tongued bees are of no special advantage to me, nor to two-thirds of the acreage of North America. And yet I find parties in the extreme Southern States, of Florida and Texas, heaping their advertisements in that very same number of Gleanings, with "LONG-TONGUED QUEENS," just as the such long tongues was the great desideratum for that Southern country, when according to the reading columns of the same paper *no one should claim they were any better.* But such claims are being, and have been, made. Let me quote a few of these claims:

"Heretofore I could only assert that the bees were superior, that they would store more honey, but I could give no reason why, except that this trait had been developed by years of selection and careful breeding; but now I can say why, or, at least, give a reasonable reason why."

And what is that reason? "They have *very long tongues.*" (Gleanings for Jan. 1st, page 32). If there was any thought about red clover in the author's mind, no hint is given to that effect.

The fact begins to dawn that bees, in order to make a better showing in their hive than the bees of another, must have long tongues." (Gleanings for 1900, page 882). These words are given in connection with bees living in the State of New Mexico, where no red clover grows, if I am correct. "It is the old, old story. In every case where we have long-tongued bees we have good honey-gatherers." (Page 881, same number of Gleanings). Not the least hint at red clover here, either. "We have now learned the secret of their great honey-gathering qualities. It exists, as I supposed, in the great length of their tongues." (Gleanings, page 813, 1900.) "Another record-breaking queen whose bees have long tongues." (Gleanings, 1900, page 844). "Long tongues and good working qualities go together." "The evidence is still piling up, to the effect that long-tongued bees are the ones that get the honey."

And so I might go on giving quotation after quotation of statements made along this line, without any special qualification, or, if any qualifications have been made they have been so hidden under a lot of rubbish, or so twisted that the reader is led to believe that long-tongued bees are just the thing he should have if he would succeed, no matter about red clover, or in what portion of the country he resides.

Now, as I hinted in the start, long-tongued bees *do* have an advantage outside of the red clover districts, or they *do not*, and to give misleading statements, or those actually false, is something that our bee-papers of the present day should not stoop to doing, not even when the motive of gain prompts its advertisers. I am satisfied that long tongues are only of advantage to those in red clover districts, if they are of any special advantage anywhere, for the reason that I have repeatedly had colonies that I considered hardly up to the average during certain seasons, (and would so mark the hive, preparing to supersede their queens in the future), that the very next season would go ahead of many others which I had marked as the best I had in the yard. And such reports have come to me from many bee-keepers in other localities.

Then, there is another thing which casts a shadow of doubt on this whole measuring matter, and that is that many admit that there is nothing of minute exactness about it. Undoubtedly, a bee with a tongue only 15 100 of an inch long can be told from one having a tongue reach of 20-100; but with the most exactness, and the nicety of the instruments used at the Melina establishment, we have this strange admission by L. R. Root, found on page 579 of July 15th Gleanings for 1900:

"All the tongues I measured would reach easily 15 100 inch. By exerting a little pressure on the head of a decapi-

tated bee just chloroformed I could get most of the tongues to stretch to 18-100."

With such an admission as this from one who has all the paraphernalia in his establishment for nicety of work, what can be expected from the thousands of bee-keepers that Dr. Miller would have set at this work? And so one of my correspondents can be excused for asking me the question, "Do you not think that one of those queens advertised on page 240 of the American Bee Journal at \$10.00, could, 'by exerting a little pressure,' have its tongue stretch so as to make a \$25.00 queen of it?"

There are times when it is necessary that a "halt should be called" by some one, and as no one has seen fit to do this, I have felt it my duty to do so, that too much money need not be sunk on this latest fad, even if we do not call it a fallacy. Onondaga Co., N. Y.

Do Bees Help to Spread Pear-Blight?

BY PROF. A. J. COOK.

OUR good friend, J. H. Martin, so favorably known to all bee-keepers, writes me from his present home as follows:

"I herewith hand you a clipping from one of our local papers. The supervisors and commissioners referred to are from Kings County. As I understand, the blight is in the blossom and so it is possible that it is spread by the bees. Would it not be well for you to comment upon this subject in the American Bee Journal and give us the truth of the matter?"

The following is the clipping:

"The supervisors have a novel question under consideration. It is whether bees are responsible for the spread of pear-blight, and what action, if any, should be taken in the matter. N. W. Motheral and J. F. Tilton, Horticultural Commissioners, gave their opinions on the matter. Mr. Motheral asserted strongly that bees spread the pear-blight, and should be condemned as a nuisance to the orchardist. Mr. Tilton is not so positive."

There is no doubt but that this question is a very important one, and certainly bee-keepers will be interested in any experience regarding it. Pear-blight has long been a serious enemy in the pear orchards in the East, and is now working fearful havoc in many places in California. At a recent institute, held at Banning, Riverside Co., there was no topic which called forth so much of interest as did this same one of pear-blight. The people there are much disturbed regarding the matter.

I think it was Prof. Arthur, of Perdue University, Indiana, who demonstrated that pear-blight is a microbe disease. If I remember correctly, he discovered the specific microbe, found that he could grow it in artificial cultures, and could by their use inoculate healthy trees. I think Prof. Arthur suggested that bees might be a means of spreading this malady. It is well known that the blight attacks the end of the twig and works inward toward the trunk of the tree. Of course the germs are in the sap, and might very likely be in the pollen, altho, so far as I know, their presence there has never been demonstrated. The pollen is carried to the stigma of the flower which, from its delicate sensitiveness, we would suppose, might be a very vulnerable point for infection. Thus the conjecture that bees spread the disease would not be an unreasonable one. Until we find, however, that the microbe is in the pollen, we certainly have a right to place a large interrogation point after this theory. Mr. Motheral or any one else who speaks with assurance in this matter, would be rash, indeed. To declare bees a nuisance on this account is entirely uncalled for.

In the early spring, the swelling buds of both flower and leaf would be the most susceptible to microbe influence which may come entirely without the aid of insects. If insects are the medium of transportation, there are many others than bees, and removing the bees would not bring security. We know that without the honey-bee, complete pollenization will not occur, and thus to declare bees a nuisance on behalf of the pomologists would be to stand in their very light, and would work them incalculable injury.

Many leading scientists of the East, especially Professors Waite and Fairchild, of the Agricultural Department, have given this matter the most careful attention. It is significant that they urge most strongly that fruit-growers take all pains to secure the presence of bees in the near precincts of their orchards. The supervisors and commissioners of Kings County can not afford to take a back step in this important matter. Los Angeles Co., Calif.

No. 4.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

Continued from page 262.

"NOW, Mr. Bond," I continued, seeing that he looked less incredulous, "had I known less about the swarming capers of bees I could not have known how to interpret these queer proceedings. By putting this and that together, however, I had good reason for the conclusion that the bees I heard and saw above the tree were the scouting party which had left the swarm as soon as it had selected a place to cluster; and that the peculiar noise they made as they flew about the top of the tree where, they knew, the swarm had settled down to wait for their return, was the signal always given on such occasions, and which all bees seem to understand."

"These seem to be trivial matters to relate just now, I know; but there are ever so many such things in the course of a bee-keeper's experience, and yet they are important."

"But," queried Mr. Bond, "what has all this to do with my way of hiving swarms? I don't, somehow, catch on."

"I'm coming to that," I replied. "These explanations were necessary in order that you might easily understand the application; which is this:

"When you take your box-hive and set it directly under, or near, the place where the swarm has settled, and after getting the bees into it, and, as you think, preparing to go to housekeeping, you leave them there. You don't even take the trouble to look at the hive again a few days after. Well, sir, in a majority of such cases the scouting party comes back soon after you leave and takes that swarm away. That is the reason I said you would find many of those hives, standing around in out-of-the-way places, empty, when you examine them."

"I lost a swarm one time under similar circumstances, when I was yet a green hand at the business. The bees had clustered on a low-hanging limb of an apple-tree. I took an empty hive and placed it under the cluster. Then I slowly—that is, gradually—shook the bees off, and thus got them all in. Then I sat down on a box not far away and watched them, intending to carry them to the apiary after sundown."

"Well, sir, while I was sitting there I heard a buzzing noise above the tree, and saw a great many bees flying about in an excited manner, making more noise, I thought, than bees ordinarily do. Before I could take a step, or think a thought, that swarm poured forth and joined the scouting party; and off they went like a whirlwind. Had I known enough to remove the hive, after securing the swarm, far enough away to be out of sight of the returning scouts, I wouldn't have lost that swarm."

"Now, Mr. Bond, I am well aware that it may appear to you that I'm telling you all this because I like to talk about bees. Bee-keepers have a reputation, you probably know, for being out-and-out cranks on the subject; and you surely know that nearly all cranks are great talkers. Well, I want to assure you that I am not 'talking thru my hat.' The information I am giving is of no slight importance. Should you conclude to keep only one or two colonies of bees instead of 50, and to apply to those two the lesson I am giving you, you would soon find out that every item of seemingly trivial detail will be useful at one time or another. If you go at the business in earnest you will soon learn that you can not succeed, all around, unless you know how to handle a swarm when it leaves the parent hive, and how to prevent its running off to the woods either before or after hiving it."

"Permit me to tell another thing before I forget it, Mr. Bond. Long before I became a bee-keeper myself I often observed the fact that those that are not fully informed in bee-lore seem to put a low estimate on a swarm of bees. If they knew what an early swarm may really be worth in a favorable season they would surely try to keep it. And, I'm sorry to say, even reputable bee-keepers are not all as well informed on this vital point as they should be. That this assertion is true I can show by relating two incidents from my experience which illustrate the fact itself, as well as the result of the ignorance that led to it. The first case was as follows:

"It was my first season's experience in bee-keeping. I had only two colonies, but they were boomers. Both had been transferred the winter previous, one from a cracker-barrel, and the other from an old-fashioned box-hive. Some time when it's more proper and convenient than just now I will tell you all about that job of transferring bees. It was interesting in several ways, I assure you. I lived in Mis-

souri then, where they tax bees, honey on hand, corn in the crib, and potatoes in the cellar—not forgetting the poor man's working tools and the poor woman's sewing machine.

"About a mile distant from my home lived a man—I shall not tell you his name because he is out of business for good—who kept bees, had kept them, he told me, 'for more'n 15 years.' He had 14 colonies, mostly in 'Langstroth hives,' when I made his acquaintance. I tried to take lessons of him that summer, but I soon found out that he had never been in Father Langstroth's school, tho he used his hive invention. Besides, he cranked several queer notions about bees—their nature, and ways of doing things—that I could not make up my mind to adopt.

"Well, one beautiful day in early May this friend sent me word that he had a very large swarm out on an apple-tree, which I could have for one dollar if I cared to bother with it. Of course I went for that swarm and brought it home in my bee-box. Within a week I got three more swarms in the same way, and at the same price, and of the same kind friend.

"I had learned from 'Bees and Honey'—an excellent little book on bee-culture, for beginners especially—how to house a new swarm so that it would lose no time monkeying around, but go right to work storing honey for me. As compensation for *knowing how*, I took from those four one-dollar swarms 350 pounds of white clover honey, in sections most beautifully filled and finisht—all before the end of the same month.

"Some time during the following October my friend sent for me one day. The messenger said: 'Would you please come down and take some honey off the hives?' But it was already late in the day, and misty clouds shut out the sun's cheery shine and heat, hence I sent word back by the messenger that I wouldn't do such work on such a day for the best friend I had; but that I would come down the first *suitable day in the morning*.

"Well, a few days later I went down. My friend pointed out to me two hives, of the 14, from which he wist me to take what surplus honey I might find. The others, he thought, hadn't done anything; and most of them had no supers on, anyway.

"The two hives he showed me were a sort of a hopper-shaped concern; 'The Mother-Hubbard hive'—or something like it—I think he called it. The bee-entrance was at the small end of the hopper, which stood grandly upon four short legs, and wore a conical-shaped hat or roof. But that cunningly devised bee-entrance at the extreme lower end of this so-called 'hive' made such a deep impression upon my then very susceptible mind that I have never forgotten it. Besides, my friend—who was evidently quite proud of those two hives—took especial pains to explain to me the superior excellence of that particular feature of the hive.

"'You see, Mr. Gehring,' he said, 'that bee-entrance, located as it is, acts as a ventilator to the hive, like a chimney to a house; for there are holes bored near to the roof, you know. Then, again, that opening acts as an automatic dirt-trap—the hive cleans itself, you see, because the dirt and dead bees fall right down thru. Besides all that, Mr. Gehring, you can see for yourself that *nice* can't very easily get into the hive by way of such a contrivance as that.'

"Well, I opened one of the hives and found quite a mess of honey, mostly in small frames inside of a sort of a box-arrangement on top of the three-cornered brood-frames, and some of it between and above these little frames. The second hive was in the same condition. I called at the kitchen-door and got a large dish-pan, into which I put the honey from the frames, and from odd spaces in the hives. Then I examined all the other hives for honey, but found none. The dish-pan full was the whole yield from 14 hives!

"When I carried the honey to the house my friend—who had kept himself out of sight while the honey harvest was going on—ventured to come to the door to settle with me, as he said. He seemed to be well pleased with his crop of honey, and smilingly inquired how much I got from those four swarms. I told him, and added that I would probably get another hundred or more from those same swarms before the season ended; and leave them enough each to winter on very nicely.

"I don't know what he thought when I told him that; but I shall never forget how he looked. It was easy to guess, however, how he estimated the comparative difference between his way of keeping bees and my way of bee-keeping, for he sold me his whole outfit before winter for the paltry sum of \$15!

"The second case to which I alluded, as I presume you remember, Mr. Bond, happened in this way:

"One of my near neighbors had two colonies of bees in his back yard—both in box-hives. One Sunday morning word was sent to me that a big swarm had come out of one of the hives and was hanging in a bunch from a limb of an apple-tree in the front yard, and that I could have it by coming after it.

"My neighbor was a member of the United Presbyterian Church, and a strict Sabbatarian; hence he could not violate his conscience by furnishing that swarm of bees a home. But I, being a minister in good standing in the 'U. S.' Presbyterian Church, had no such scruples to bother me; hence I secured the swarm—cut the limb with a small saw, and carried it home with the cluster hanging to it—and hived it, and gave it a frame of brood, and two of honey, that same Sunday.

"It was a late swarm, and it was a rather poor honey season; but that swarm filled, and finisht nicely, two supers of 28 sections each. One evening I took four of the nicest sections and presented them to my Presbyterian brother, and told him all about that swarm's doings under my care; and that, if he wanted it, I would sell it to him for \$10, hive and all."

(To be continued.)

No. 4.—Drone-Bees and Their Utility.

Can We, and Shall We, Control their Production?

BY C. P. DADANT.

IF the reader remembers my previous articles on the subject, he knows that we have plainly shown that there is a decided advantage in decreasing the number of drones in hives that are undesirable for breeding purposes, and that this advantage will be derived, in part, from a greater saving of honey. The approximate amount of profit to be earned from the prevention of drone-rearing, or from the excess of it, is, however, difficult to establish. By following the method mentioned, of removing drone-comb, and replacing it with worker-comb, we not only prevent in a large measure the production of the idlers, but increase our chances of a greater production of worker-bees, which, costing no more to rear, will yet help increase the stores instead of consuming them.

In the relation of my summer trip to Europe, and of my attendance at the International Bee-Keepers' Congress, I mentioned the discussion that took place on this very question. The matter had perhaps more importance to the bee-keepers of Europe than we could place upon it, because of the very great divergence of opinions expressed there, by some noted bee-keepers. A French bee-lover, by the name of C. M. Weber, has written a poem on bees, somewhat after the fashion of the English Dr. Evans, and in this work he has asserted that each drone consumes during his life, at least five grammes of honey, or in other words, that it takes but a hundred drones to consume, from their birth to their death, over a pound of honey. If we take such an assertion seriously, the honey consumption by the drones of a colony would be enormous. This would mean that the drones produced in a square foot of comb could do away with 50 pounds of honey. To me it is almost to be considered as an absurdity. Some other men have gone still farther and have endeavored to prove that a drone may consume as much as 11 grammes of honey in his life, which would be the equivalent of a pound of honey for 40 drones. These assertions, however ludicrous they may appear, have caused considerable comment, and some discussion, and the experiments that were brought to light before the Congress were evidently intended to refute these too-magnified ideas of the utility of removing drone-combs.

A gentleman by the name of Dufour gave notice of quite extensive experiments which he has made on the subject, and reported weighing 10 colonies at different times during the summer. Half of these colonies contained but little drone-comb and consequently produced but few drones, while the other five contained many drones, and the total result was a difference in production of 15½ pounds of honey in favor of the hives having the least number of drones. The necessity of experimenting on a large scale, in matters of this kind, is shown by the fact that out of these 10 colonies two were selected which were apparently of equal strength, to be weighed regularly, and the difference between the two, in the results, was in favor of the one having the most drones, but it was a mere trifle, less than a pound. So we must recognize the wisdom of this

man's statement, that extensive experiments are needed to get at a good idea of the proportion of gain secured, by the removal of the excess of drone-combs.

But even this rather insufficient experiment strongly evidences the advantage of the removal of drone-comb, for aside from the desirability of preventing the production of inferior stock for reproducing purposes, the narrow margin of profit there shown is more than sufficient to repay us for the labor. In fact it repays it many times. Supposing the increase in production to be only three pounds annually per colony of bees, (where the drones are reduced to the lowest possible number), these three pounds will pay the first season for all the labor and the cost of the worker-comb used, and so in the very first year we already have collected back the cost of the exchange. But we must remember that the combs of a hive last many years. We have colonies in which the entire set of combs has not been removed for over 30 years, and during each year the saving made repeats itself without additional cost, so that we are actually making an investment bringing us 100 percent annually.

I see it asserted that queens will lay drone-eggs in worker-combs rather than do without drone-cells. I have never seen this in any but old queens whose fertility is already impaired. We have, for years, made a practice of removing drone-comb wherever found, and have never noticed that it led to any such results; we have never known bees to tear out any comb to replace it with other comb. The only instances where such a change was made were in the case of combs that had broken down by heat under the weight of the honey, or when old combs had been thoughtlessly removed by the apiarist without being replaced by other combs.

I earnestly solicit those who have leisure and opportunity to make extensive experiments on these matters, reminding them that it is necessary to make these in the most careful manner, and on a scale sufficient to assure the results against possibilities of inequality in the conditions which would materially affect the total returns. I am satisfied that such experiments will clearly evidence the advisability of controlling the breeding of drones in the measure of our opportunities.

Hancock Co., Ill.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Get a Bee-Book.

For fear some beginner may not have read them, I want to repeat here some words of the editor on page 244, that should be emphasized:

"First get and read a good bee-book thoroly, then get the bees. Then read your book again. Then you will be ready for a good bee-paper, and, very likely—more bees."

C. C. MILLER.

A Beginner's Questions.

1. I have a hive offered me. When I receive it what would be the first thing to do to have it in trim for the honey-flow?

2. I have a hive that about two years ago a colony died in (of what cause I have no idea)—would it be safe to put another swarm in?

3. The cells are filled with some kind of stuff somewhat resembling a fine sawdust, very filthy, and a few webs, but I can not find any worms. Is there any way to save them?

4. Wouldn't it be a good plan to winter two or three colonies, outdoors, in a kind of enclosure made of boards, back, two sides and a roof, with an opening to the south?

5. When would you put supers on? WASHINGTON.

ANSWERS.—1. I am a little at a loss to know whether you mean a hive or a colony of bees. From your second question I should judge you mean a hive, in which case I should say that probably nothing more is necessary than to see that the hive is clean. If it is an old hive, it is quite

possible that it may need a thoro cleaning out. If you mean a colony of bees, the first thing to be done depends upon the first thing that is needed. That might be a good many different things, and some of them might be supposed and answers given accordingly, but even then the very one needed might be omitted.

The first thing that is needed more than all else is a thoro familiarity with a good text-book on bee-keeping. If you have only a single colony of bees, it will pay you well to become familiar with the contents of a text-book. When you have done that, there will be plenty of questions that will come up that may not be fully explained in the text-book, and this department will be ever ready to help out.

2. It will be entirely safe unless there has been foul brood in it. You can find out whether foul brood has been in the neighborhood. If it has not, there can be little risk in using the hive. If it has, then you must try to find out whether a diseased colony has been in that hive, and act accordingly. If you use combs upon which a foul-broody colony has died, you may safely count on the appearance of the dread scourge. But the hive itself, with no combs in it, Mr. McEvoy, the foul brood expert, says may be safely used.

3. Very likely what appears like fine sawdust is pollen, and it may have been worked upon by some kind of insect. The webs are likely the work of wax-worms, but the freezing of winter has gotten rid of any wax-worms that were present. If these combs are given one or two at a time to a strong colony of bees they will be cleaned up, and if not too badly riddled by the worms will do good service.

4. Such an arrangement is often used with good results.

5. One way is to watch for the first beginning of white wax put by the bees upon the upper part of the combs and at once put on supers when it is seen. Another way is to put them on when you see the first flowers upon the plants from which you expect your honey harvest.

A Beginner's Questions.

Last September I bought some Italian bees in double-walled Langstroth hives, "Langstroth on the Honey-Bee," Cook's "Bee-Keeper's Guide," and the American Bee Journal for one year, which I enjoy very much. My wife says that I have had bees in my bonnet all winter. But I notice that I'm not the only reader of the Bee Journal in my home!

May 1st I return to the country and my bees, and there are several things that I would like to know which do not seem to be in the bee-book.

1. How can I tell if my colonies are strong?

2. How often should the hives be inspected? and how often can they be without injury?

3. Should all the frames be taken out? (to be out at the same time), and how long left out?

4. How can I tell if the frames are "well covered?" and does "frames well covered" mean all the frames in the brood-chamber?

5. Are particular frames used for brood? and honey?

6. Do a May queen and nucleus usually yield surplus honey the first year?

7. Do queens go out for a flight after their wedding-trip?

8. Is there danger of using too much smoke?

9. How may I tell if there is a good honey-flow?

10. How long does it take honey to ripen?

11. When is the capping of honey done?

12. After being stung, what is the best method of removing the stinger?

NEW YORK.

ANSWERS.—1. Look at 'em and see. If in April you find combs covered with bees, and brood in them, you may brag that you have a strong colony. If you find only one or two frames covered, it is very weak. If four, it will come out in good form.

2. That's a tough one. If you mean for the good of the bees, from one to half a dozen times a year may do. If you mean for a crazy-headed fellow who is just beginning, three times daily except Sundays will be about right, also rather rough on the bees. Fortunately, however, they can stand a good deal, and if the hive is only opened when it is warm enough for them to fly freely there is perhaps no appreciable harm if they should be opened once every day. At any rate, remembering how crazy-headed I once was myself, and how little I have recovered from it in all these years, I'm not the man to put any restrictions on your tinkering with the bees, always providing you do it when warm

enough. It may not be a good thing for the bees, but it will do you enough good to make up.

3. Generally no need to take out more than one or two so as to make room to move the others freely in the hive. Indeed, if taking out the dummy leaves room enough for easy handling, there is no need to take out any except the one you have in your hand. If, however, you have an empty hive to put the frames in as you take them out, there is no harm in taking out all for the frames will keep each other warm in one hive as well as another. There are just the two things to guard against in taking frames having combs out of the hive—cold and robbers. If you don't chill the brood, and if you don't start robbing, there is little danger of too many frames being out, or of their being out too long. If obliged to open a hive when the temperature stands only 60 or 70 degrees, try not to have a frame out more than two or three minutes. Perhaps you can judge better by the flying than by the thermometer. If the bees are flying very freely, call it warm; if very few are flying, meddle with the bees as little as possible.

4. A frame is well-covered when there are enough bees on it to cover the whole comb, the bees being close enough to touch each other all over the frame, altho some parts of the frame may not be entirely covered, and some may have been piled on one another three or four deep. I don't know whether "frames well covered" means all in the hive or not—depends on the connection. If you say a colony has its frames well covered, I should say you meant all; otherwise you would be likely to specify the number.

5. No, and yes. The frames in the brood-chamber are all alike, and if you have a set that are empty you may change them indiscriminately without doing any harm. They are unlike in this respect, that you will not find the two outside combs with as much brood as others, if indeed you find any brood in them. They will be mostly filled with pollen and honey. The rest of the combs will contain both brood and honey, those toward the outside having more honey than the central ones.

6. They may in a good season.

7. Probably not.

8. Decidedly. Use only enough to subdue the bees, and if they show fight use a little more, and keep using it occasionally if you need it. Generally, however, there will be no occasion to use it the second time.

9. Note whether there is an increase of honey in the hives. If the honey-flow is good the bees seem in more of a hurry and more of them are flying. When they are doing a big business some of them will drop down in front of the hive with their heavy loads, and will have to rest there a bit before they rise to enter.

10. I don't know definitely enough to give a categorical answer. The weather, the source of nectar, and other things have to do with the case, and the time may vary much. Sometimes it seems to ripen within two or three days, and sometimes in as many weeks. A section may be two or three weeks from the time the bees commence storing in it before it is entirely sealed, in which case it could not be said that the whole of it was ripened in less than two or three weeks, and yet it would hardly be right to say that any part of it was two weeks in ripening, for the first stored in the section was probably ripe some time before the last, and the last may have been gathered less than a week before it was sealed. While it is true, as a rule, that honey is ripe when it is sealed, there seem to be cases in which it remains unsealed after being ripe, and others in which it is sealed before it is ripe. If you insist that I shall say how long on the average it takes honey to ripen, I should say that in this climate it takes about a week. But I frankly confess I don't know, and shall be glad to learn from some one who has made a study of the matter.

11. As a rule, when ripe; but as before said, there may be exceptions. The exceptions, however, are probably not at all common.

12. The most natural way that would suggest itself to an inexperienced person would be to take hold of it and pull it out just as you would a thorn or a splinter, and the question might seem like a foolish one. But if you take hold to pull it out in the usual way, you will grasp the poison-bag which remains attached to the sting, and you will squeeze some of the poison into the wound. Scrape it out with the thumb or finger-nail. A quicker way, and one that is just as effective, you will learn by experience when stung on the back of the hand, where a large proportion of stings are received. Slap the back of the hand quickly on the leg with a sort of wiping motion the instant the bee strikes the hand. That will mash the bee, and at the same time it will wipe out the sting if you use force enough.

Swarming Management, Etc.

1. I am just a beginner in the bee-business. I hived some 60 swarms last spring, and some eight this spring, and I have my first yet to lose. I always move the swarm. Now what is the difference? I see some advocate moving the old hive.

2. I have my bees on the lowlands of the river, so I have to scaffold up for them, five or six feet off of the ground. Can I set them on the ground during the summer, then raise them in winter, so as to keep them above high water? I have been thinking of putting them on the ground this spring.

CALIFORNIA.

ANSWERS.—1. Putting the swarm on the old stand and moving the old hive is not done for the sake of keeping the swarm from deserting, but to throw the flying force into the swarm, making it strong for storing, and also preventing the issue of after-swarms. If you will try it you may find that with this practice you will get more surplus from the swarm than you will get from both if you put the swarm on a new stand.

2. I see no reason why it will not work all right to lower the hives during the time it will be safe, and it will certainly be much more convenient not to have them so near the sky when working at them.

Perhaps Bee-Paralysis.

What can be the matter with my bees? The colony most affected has almost perished. The bees crawl or are dragged out of the hive and they then crawl off in the grass to die. Some try to fly but fail. Where one lies during the night a yellow stain is sometimes, but not often, left. They have been that way two months. I am feeding them honey. They are in Langstroth hives.

ARKANSAS.

ANSWER.—From the little of description that is given it is not possible to be certain, but the great probability is that your bees have bee-paralysis. If that is the trouble, you will find the affected bees have a trembling motion, are inclined to be black and shiny, and are pulled and dragged about by the other bees. Many cures have been offered, but unfortunately none of them seem to be reliable. It is possible the disease may disappear of itself, and it is possible it may keep on with its deadly work. Some have confidently claimed a cure by making a diseased colony exchange places with a healthy one. It would do no great harm to try the experiment.

Dividing Colonies.

I have 10 colonies and wish to divide them so as to get the white clover honey. I divided last year and put one-half into each hive, but lost the white clover crop, as they put it all in the empty hives, or on the four sheets of foundation that I put in place of the four that I took out. I use the eight-frame dovetail hive. I wish to requeen from two queens that I got last fall. Would I better use the nucleus plan, as I can get that out of the Journal or the "A B C," as I have both?

ILLINOIS.

ANSWER.—You will do well to use the nucleus plan both for rearing your queens and making your increase. That will allow you to keep most of your colonies strong for storing. When you cut a colony right in two, neither half is strong enough to do much storing; but you can from time to time draw a frame or two of brood and bees from a colony that is storing without very seriously interfering. Of course it does make a difference but nothing like the difference it does to take away half the force.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one yearly subscription to the American Bee Journal at \$1.00.

The Premiums offered this week are well worth working for. Look at them.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

INSECT HONEY ON "CLOUD REST."

As told on page 196, Prof. Cook certainly found scientific "nuts and raisins" on Cloud Rest in the Yosemite—great drops of nectar secreted by pine aphides. And it was doubly blessed in having intelligent tasters at hand who did not know what the origin of the nectar was. Quite interesting to see that all the party pronounced it of excellent flavor. If some of us should say that bees work on aphide secretion and clover at the same time, and mix the proceeds, and that the mixture passes readily for clover honey—well, the story would hardly "go down." Please remember, therefore, that Prof. Cook contributes a positive case of this sort. We must not ignore the facts; and the fact seems to be that some insect honey is excellent, and some abominable. Probably also there are all intermediate grades.

DOES LOSING THE STING KILL THE BEE?

Right this way to see an interesting little fight. Let's have a "shindy" between Prof. Cook, who has proved by direct experiment that the loss of the sting kills the bee, and those others who have proved by direct experiment that it doesn't. Perhaps it is rather soon for me to act as umpire, but nevertheless let me have my say. Suppose an oze should seize a dozen children and pull a leg off each one. Would they all die or all get well? Neither. Some would die and some get well. In deficit of evidence this is to be presumed of all very serious wounds in all creatures. As to case in hand, the matter is still more complicated. Sometimes the wound is very serious and sometimes it isn't, depending upon the size of the lump of tissue pulled away with the sting. Losing the sting only should no more kill a bee than losing her horns in a fight kills a cow. But if you should jerk off the cows horns in such a way as to carry the whole top off her head away too, she would probably die. Again, stingers are mostly aged (presumably) and aged bees in June have but a very short span of life left anyway. Wonder if this fact has not been forgotten in some of the "direct experiments." Page 197.

BEE-KEEPING FOR INVALIDS.

Yes, from one point of view, bee-keeping is hardly the thing for invalids—calls for lively stepping around, long hours, and sometimes for heavy expenditures of strength. But somehow one successful bee-keeping invalid, like Mrs. Axtell, rather extinguishes considerable argument on the other side. And here's a good sentence from Mrs. A., worthy to be printed large on the beginner's smoker, or some such place: "Pay little attention to what your neighbor advises, unless you know him to be a practical apiarist." The neighbor wise and gray, who has had "more or less bees around my place all my life," is especially a dangerous snare to the beginner. p. 197.

THOSE TALKS TO BEGINNERS.

Here's compliments to the talks to beginners by Mr. Gehring. They are good. But then, every new dog must expect to be snuffed at and snarled at *some*, and I'll see if I can't find a place where I can snap my teeth together. Ah, here it is! "They give up as soon as they find themselves prisoners—always and everywhere." This is very correct as a general truth; but my idea is that there are occasional exceptions, that they do sometimes ignore everything else but the consuming passion to find a vulnerable place and put in a sting. The bee under your veil almost always feels intimidated and tries to get out; but once in awhile one will proceed to business. I think this takes in two ways, sometimes by being too infuriated to notice the plainest evidence of imprisonment, and sometimes by taking a few turns around, sizing up the situation, and then deciding that a fellow who has sworn to die in the attempt does best to "strike home" at once. p. 199.

NECTAR-GATHERING MICE.

Our bees, of course, have the other insects and the humming-birds as competitors; but it is news to be informed that there are nectar-gathering mice. (Apologies to the scientists who want them called Marsupials; but the picture says they're mice). Certainly animate nature is amazingly versatile in its forms. Page 212.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

ATTRACTIVE HOMES AND SURROUNDINGS.

The home circle like everything else about us, is wondrously affected by its environment. I said none too much about the kind word and the thoughtful act in the home. I spoke truly of the marvelous influence of the flowers in the home. I think it was Henry Ward Beecher who said, "Show me the books and the papers in a household, and let me know the company which frequent the same, and I will rightly describe the people of that home." The home is not simply confined to the inside of the walls that domicile us. The immediate surroundings of the house are of equal importance in their influence to refine the character and mould the tastes.

Some years since, the village of Kalamazoo, Mich.,—it was larger than a great many cities—gained a wide reputation, not only for being the largest village in the United States, but for being one of the most beautiful towns in the country. It was not that the houses were palatial. Many of these were cottages, and not a few were very humble in their dimensions and architecture. But the thing that attracted everybody, and gave Kalamazoo its well-earned fame, was the beautifully kept lawns and lovely flowers, shrubs and trees, usually arranged with the skill of an artist, which adorned nearly every home in that beautiful village. I hardly need say that the people of Kalamazoo were exceptional in refinement, intelligence and enterprise. Loveliness like music charms every one and will certainly attract the best to its near presence. Kalamazoo had its fine public library, its ladies' club which attracted large attention, and its drives and boulevards which were enjoyed by the many visitors that delighted in spending their summer outings in this lovely spot.

We may not all be so fortunate as to live in Kalamazoo. We may be so unfortunate as to have neighbors who care little for neatness, order, and beauty. We can, all of us, make our home the pride, not only of those who occupy it, but also the pride of all our neighbors. Even those who are lacking in taste or are too indolent to make the exertion which fine grounds require, often show their appreciation when company comes to visit them. As they walk or drive out, they are very sure to pass by the orderly, well-cared-for places of the town or neighborhood. How many reasons there are why each of us should do all in our power to make our grounds the most lovely and attractive of any in our region. What sincere pleasure it gives us as we daily watch the growth of the beautiful plants and trees, and think of the part we have had in their arrangement and fashioning. Whatever gives us pleasure, as we have shown in a previous article, is sure to add to health and longevity. Thus we score again for the neat home grounds. We lover to have our immediate friends refined and cultured. I wonder if children that are brought up from the earliest years, where everything tells of neatness and order, will ever fail to receive something of real refinement. Surely if beauty about the home works such blessedness in its members, we may tally again for home adornment. We know what the Scripture says about the heaven, and how all the meal was transformed. Can any of us have a higher ambition than a wish to plant this heaven that shall tend to make all the homes of our vicinity attractive and beautiful?

I believe I know just why Kalamazoo gained such a wide reputation for its superlative attractiveness. There is no question but that an exceptionally large number of the first settlers of that beautiful little village came from just such homes as we have been trying to describe, and were so attached to beautiful surroundings that they gave first attention to making their own homes so neat and lovely that others who came to the town, even the less enamored of such beautiful things were at once led to follow the good example already set. Soon, it would be so noticeable if any slovenly place was permitted to disgrace the village that no one had the bravado to set the example, and thus the whole village became famed throught the State and country.

Possibly we bee-keepers stand in special need of some exhortation in this direction. In California, especially, the apiary is off in some canyon or on some secluded mesa, and is likely to be seldom visited by any but the bee-keeper and his family. Thus the stimulus which comes from rubbing against the world and from its criticism is wholly lacking, and we are likely to become largely indifferent as regards the appearance

not only of the apiary but also of the cabin or house in case we live near the apiary, and all the surroundings. If we do make the apiary our home, and the family shares its pleasures with us, we certainly can not afford to be neglectful of these adornments which will go so far and do so much to make our loved ones possess of a personality which will honor and delight us and bless the world. Here again we score heavily for home adornment.

There is another reason why we should all look to it that our homes are made as attractive as our means and time will permit. By giving a little more time, we can purchase our flowers, shrubs and trees while very small and so at a very slight cost. By giving study to the grounds of others we can learn what are the most beautiful plants and shrubs. This will not only improve our observation but will be a delight in itself. Thus as we come to select for ourselves we shall make few, if any, mistakes. By giving a little time each day we can do all that is required, and hardly feel it either in time or labor. We thus keep in touch with all about our home and it soon becomes so much a part of us that it develops within us a love for the place which does so much to sweeten life.

The above is not simply theory with me, for we in our own home have tried to carry out what I have suggested above. California has much to encourage one in this kind of an undertaking. The flowers and plants here are so varied and beautiful that it is a wonder that every one does not feel moved to bring them to his own dooryard. The soil here is also so marvelously productive that a single season will suffice to clothe a bare place in the landscape with beauty and verdure that would require years in the more tardy East. Wherever we go, whether in the country or in the city, we are all eagerly watching for vines, flowers or shrubs that are more lovely than those which we already possess. Our excursions are therefore more enjoyable, and we have been able to select the most beautiful flowers, shrubs and trees that can be found anywhere. We each of us, then, planned how we would have our walks and drives, where we would put the lawn and where we would put the various plants that they might show off to the best effect. We then compared our plans and selected the one which all agreed would serve best for our especial place and purpose. We then set out the plants and all have had a part in cultivating the ground, adding the needed water and using the pruning shears. What a bond of interest this forms in the home! What delightful table-talk it calls forth, and how it prolongs the meal-time hour. Thus we see that the advantages in all this beautiful work of home adornment reach out in many ways, and pay a tremendous interest on the capital invested.

We are all very fond of grapes and have sought out what we believe are the best, selecting from both foreign and American varieties, and have planted them in two rows about eight feet apart. We have used inch gas-pipe and have made arches spanning the difference between the rows of grapes. The vines run over this and form a beautiful arbor. This not only affords a shady place to sit and read, and, in the autumn, to

eat, but also hides the clothes-line which in the dry climate of California has little need of the sunshine to make its position suitable.

On the north side of our house, similar arbors of English ivy and other beautiful vines form another cozy nook. We utilize this not only for rest and shade, but under its protecting shade we plant the exquisite ferns, the charming begonias and the graceful climbing asparagus. These arches keep the climbing rose-bushes—wisteria, solanum, tecomis, etc.—away from the house, and give a grace and beauty that must be admired by all. Surely, the home-circle does not know what it misses if it does not do all it can in this matter of adornment of home grounds.

We have also studied up the matter of fruits, and have added such fruit-trees as we think will contribute most to the comfort and satisfaction of the family. In California, this is a matter of exceeding interest as almost all the fruits known to our country do well here. I remember visiting many apiarists in Michigan who had not lost sight of these matters which engage our attention to-day. I remember very well the home of Dr. Whiting, of East Saginaw, who will be remembered as such an enthusiast in all matters pertaining to the apiary. I remember with what pleasure Dr. Whiting showed us his grapes and his trees, and how proud he seemed to be, as he gave us the beautiful grapes and fruit. Much as Dr. Whiting enjoyed his bees, I can but believe that he received greater satisfaction from the fruit which graced his own table, and regaled the appetite of his fortunate guests. I have visited many other bee-keepers in many States of the country, and not a few of them had homes that might be the envy of any one. Many, like Dr. Miller, loved the roses and other flowers, and many of them have adorned their homes in a way to offer an object lesson of real value to all passers-by.

I do not believe it is necessary to secure the services of a landscape gardener in carrying out these suggestions. There are very few of us who, if we carefully observe the places of others, especially those that please us and have cost about the same expense that we are able to make, can not fashion our own grounds in a way to please us and receive the approval of the public. The very study that we shall give to the grounds of others will be a wholesome pleasure; and valuable in the added knowledge which we shall receive. It is also valuable and even more delightful to talk these matters over with those whose beautiful places show that they have taste and appreciation. I have visited almost every place in Southern California. Some of these places, like Montecito and Pasadena, are to California what Kalamazoo is to Michigan. With what exquisite delight I lookt upon and studied the many beautiful places of these cities. How I have enjoyed talking with the owners and finding out the principles which they had used so successfully in adorning their own beautiful grounds. With what especial delight did I take Mrs. Cook to enjoy with me the environs of the second city, and with what eagerness I lookt forward to a promised visit with her that we may enjoy together the incomparable beauty of the little suburb of Santa Barbara, known as Montecito.

Farm Wagon Economy.

The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., who make this Electric Handy Wagon and the now famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

ELECTRIC

This wagon is composed of the best material throughout—white hickory axles, steel wheels, steel bounds, etc. Guaranteed to carry 400 lbs. These Electric Steel Wheels are made to fit any wagon, and make practically a new wagon out of the old one. They can be had in any height desired and any width of tire up to 8 inches. With an extra set of these wheels a farmer can interchange them with his regular wheels and have a high or low-down wagon at will.

Write for catalog of the "Electric Line" to Electric Wheel Co., Box 10, Quincy, Ill. Please mention Bee Journal when writing.

Bees in Fair Condition.

I put all my bees out April 20th, and they are only in fair condition, being light in weight and also in bees. I lost 6 thru starvation, and one was queenless. The starvation was due to not being able to put them into the cellar myself. I had 230 colonies.

N. STAININGER.

Cedar Co., Iowa, April 23.

Egyptian and Hungarian Bees.

I have yet to see the first Egyptian bees. Many years ago Mr. J. W. Winder, of Cincinnati (notice of whose death I was very sorry to see in last year's Bee Journal), offered to send me an Egyptian queen the succeeding spring, but he lost all of them during the winter which followed.

I have had more experience with the Hungarian bees, as I once took care of a colony for an old friend, who has since past away. I

To make rows up, use Sharples Cream Separators. Book 'Business Dairymen' N. Oct. 212 free. W. Chester, Pa.

FOR SALE

I have 40 colonies left out of my 100 I advertised last month—all on 8 self-spacing Hoffman frames in dovetailed hives, two supers with each hive, full worker-brood combs, in lots of 15 to 25, \$2.50 per colony; or the entire lot at \$2.00 apiece.

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00.)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

hardly know how to describe these bees, but they look much like the bees that many now call Carniolans, still they are different, being of a dirty bluish gray, or what some of my friends used to call a "wild pigeon" color. They are the quietest and gentlest of any bees I ever worked with, and I liked them except for their falling from the combs and their inclination to excessive storing of propolis. But a bad winter carried them off, as it did the Egyptian bees.

I should be glad to know what has become of these two races of bees, if any fellow bee-keeper can tell me.

WM. S. BARCLAY.

Beaver Co., Pa., April 12.

Weather Unfavorable for Bees.

This is cold weather for bees. Mine came out for a flight April 3d, and those that were alive had a good one. The loss was 12 percent, and if the weather does not change soon I am afraid we shall lose more. There is such a cold wind blowing from the northeast that I am unable to open my hives, but I hope a day will soon come when I can look them over. I know that some of mine are very light, but I am hoping for the best, and am very much interested in bees.

I would like to know what a bee-house is; where it keeps itself; and what the work is that it does in a bee-hive.

C. H. YONG.

Manitowoc Co., Wis., April 24.

Bees Bringing in Pollen.

Bees came thru the winter nicely. I put them out April 10th, and they brought in pollen an hour after being put on the summer stands. We had heavy frosts April 19th and 20th, the temperature being 21 degrees above zero, but since then the bees have been working lively. They are stronger than usual.

I am getting better slowly, but can not do much as yet.

C. THEILMANN.

Wabasha Co., Minn., April 24.

Blacks vs. Italians in Brood-Rearing.

I wintered 42 colonies of bees on the summer stands with no protection, and did not lose a colony.

I think black bees far ahead of Italians in regard to brood-rearing.

C. C. REAM.

Klamath Co., Oreg., April 18.

Severe Winter Causes Heavy Loss.

My loss so far is 10 out of 25, and I hope the limit has been reached. The weather was so severe all winter that the bees could not reach their stores, so I have been feeding the honey to the survivors.

MRS. C. A. BALL.

Oelids Co., N. Y., April 22.

Bee-Keeping and Bears in Florida.

The secretion of nectar from flowers in this locality has been rather poor so far this season. There have been cool winds and heavy falls of rain. Fruit-trees bloomed profusely, and are now thru with the exception of Burbank plums, which are now opening. Ti-ti bloom is very abundant now, and has been for several weeks, and is a great favorite with bees.

There is an apiary located at the mouth of

the Choctawhatchee River, near a swamp 15 miles across. The damp, rich soil produces many honey-yielding plants, and furnishes a secure retreat for bees; one visited the apiary, and ate and destroyed 15 colonies. On an arm of St. Andrews Bay, where an apiary is located, a bear destroyed several colonies, but was shot, and much meat secured and a fine pelt.

Mrs. L. HARRISON.

Washington Co., Fla. April 16.

Last Year an Average One.

My bees wintered well. Last fall I put 54 colonies into the cellar, and last week took out that number in fine shape. Last year was an average one with me, as I got about 1,800 pounds of comb honey.

R. A. HUNT.

Fillmore Co., Minn., April 16.

Hard Winter on Bees.

I have lost 4 colonies out of 16 wintered on the summer stand. It was a hard winter for bees, there being no chance for them to fly.

JOSEPH N. ROWLEE.

Oswego Co., N. Y., April 23.

Bees Building Up Nicely.

Bees are building up nicely, and are swarming, but not storing very much more honey than they consume. Our first honey harvest will be from the second cutting of alfalfa, which will be in May.

I appreciate the American Bee Journal very much.

Mrs. A. BOWEN.

Merced Co., Calif. April 16.

Gathering Pollen and Honey.

We have had a very backward, cold spring, but the bees have wintered well, and it is nice weather now. They are bringing in pollen and some honey from the woods. I have 70 colonies, having lost 6. The prospects are good. Clover wintered splendidly, both white and alsike.

DANIEL STUART.

Ontario, Canada, April 27.

Bees Gathering Honey.

My bees wintered tiptop, and are bringing in lots of honey today. The American Bee Journal is all right.

GILBERT BROWN.

Fulton Co., N. Y., April 27.

Wintered With Small Loss.

The bees have come thru the winter in good shape, with a loss of 4 colonies out of 69. It is snowing here today, and the temperature is 36 degrees above zero.

EDWIN HEDDINGS.

Livingston Co., N. Y., April 19.

Bees in Eastern Pennsylvania.

I am starting in the bee-business in a locality which I suppose is about the poorest in the United States. Bees are kept in small quantities by almost every farmer in the neighborhood—from one to five colonies—in the old-style box-hive. They all complain of little surplus honey, only from 5 to 15 pounds from their best colonies. I know of some that didn't get a pound for three years in succession. Bee-plants are very scarce around here, except that of fruit-bloom and white clover, which, some years, are quite plentiful. Almost every foot of soil is cultivated, and all weeds and wild flowers along the fences and roadsides are cut down. There is no buckwheat raised here any more, which is used to produce large quantities of honey. We need the long-tongued bees very badly in this part of the country, as there are hundreds of acres of red clover around here, where barrels of honey are going to waste.

I bought several colonies of black bees last spring at \$1.00 per colony, and expect to transfer some of them into dovetailed hives, and later on supply them with Italian queens.

F. M. MAYBERREY.

Montgomery Co., Pa., April 18.

Tennessee Queens!

Fine lot of Choice Tested Queens reared last season, daughters of select imported and select golden queens, reared 3/4 miles apart, and mated to select drones, \$1.50 each; untested warranted queens, from same breeders, either strain, 75c each. Quilts or No Quilts.

At the Ontario convention, reported in the Canadian Bee Journal, 18 were in favor of quilts and 12 opposed.

Sugar for Feeding.

It is good in the fall, perhaps better than honey; but for spring, honey is away ahead. Says A. Alberti in Deutsche Ill. Bztg. The sugar needs a digestion that the honey does not, and in the fall and early winter this matters little because the food is taken in such small portions, but when breeding begins in late winter or spring, then it is consumed in large quantities, and converting so much cane-sugar overburdens.

Hoffman Frames.

These have been strongly championed by Editor Root, but he now admits that there are localities in which propolis is so bad that Hoffman frames are impracticable.

A Plan of Producing Comb Honey.

Here is a matter for you to try in your apiaries. It is the system to be used with shallow divisible-brood-chamber hives. You have eight-frame hives: Take two of these for a brood-chamber thru the spring. Manage so as to have the brood as much as you can in one of the chambers, say by having the brood-nest in the upper one, and spread it and maintain it there. These combs solid full of brood. The success does not depend on this getting the one set of combs solid full of brood, but to obtain best results it will pay to do this. With this double brood-chamber there is so much room you keep down the swarming fever, and I think the room to spread, especially downward, gives a greater vigor of work than a crowded hive.

Ten days before the flow begins, put the queen in the lower-chamber with a little brood—one comb with any amount of brood will be plenty; an excluder on this, and the rest of the brood on top. At the end of ten days, when the flow is just starting, take to a new stand the lower hive with the queen, and put the top-chamber on the old stand with nothing but its *sealed* brood and no queen, but give a virgin queen or ripe, protected cell, or wait two or three days and give a queen or cell. Give only a cell or a virgin queen, because the brood is *all sealed* that is left on the old stand; and while the virgin is mating, and getting ready to lay, the brood is hatching; so when she does begin laying, the last of the brood is about ready to emerge, and your colony is just in the condition of a colony that has swarmed naturally, and their young queen just ready to lay, except that you have kept the strength of the colony on the old stand, and have but one section of work. As the brood and laid the brood-combs were filled with honey; but as that young queen begins to lay, that honey goes up to the sections out of her way, and you have no swarming, either.

This system anticipates quite a contracted brood-chamber left on the old stand, which would be the result with one section of a divisible-chamber-hive, hence there would not be any great amount of honey stored in it during the time the queen was not laying. To make the best test with the eight-frame hives, I suggest that you use but six to the body, using a dummy at each side; thus you have a twelve-frame hive before the separation at the start of the flow, and six left when divided.

The whole plan contemplates a big hive up till the flow, then a very small one on the old stand, and yet all swarming effectually controlled, the force of fielders right where they

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal
one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythes blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost. No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools, the holes in the standard are used instead of the notches.

will do the most good. The old queen never stops laying, and goes right on and builds up a good colony in her new location.

This is no idle dream, and I ask that you have it tried in your apiaries this season, to be written up later after trial. I have for years been studying the plan, and, to some extent, experimenting. I think I am the pioneer in it, the other man, and a good apiarist in this State, has also used the principle, coming at it independently of me. If I have the success I anticipate for it, it will be the system with divisible-brood-chamber hives.—R. C. ALKIN, Larimer Co., Colo.

[Our readers will remember that about two years ago I advocated a plan very similar to this—that is, I practiced running two eight-frame brood-chambers for the purpose of getting powerful colonies for the production of comb-honey; then when the honey-flow was fairly upon us I crowded this colony all into one brood-chamber and one or two supers containing sections and foundation. Sometimes I gave such colonies a shallow extracting-super, and after the bees had them well started I took them off and substituted the comb-honey supers. There were a few of our readers who condemned the plan as impracticable and unorthodox; but I know that for some localities, and for some seasons at least, it is all right. Mr. Alkin's plan is, perhaps, an improvement on mine, and I wish a good many of our readers might try it and report at the end of the season.]—E. R. Root, in *Gleanings in Bee-Culture*.

Long Tongues and Red Clover.

J. D. Evans, in the Canadian Bee Journal, thinks that instead of working for long tongues the effort should be to obtain a new clover by crossing red and white, or red and alsike. In the same journal, Ha Michener, referring to the strange circumstance that during a certain season one kind of bees would excel, and show no superiority at other times, says:

I have become thoroly converted to the "long-tongue" idea, and believe that explains it all; there is no mystery about it. There will be more difference during clover honey because the long-tongued bees can work on red clover, especially mammoth or large red clover, "and when the buckwheat and goldenrod honey come we will not see all of that difference." Why? Because hybrids, or even black bees, can work as well on buckwheat and goldenrod, and it is the same early in the season on the wild red-raspberry.

My son, E. L. Michener, living further from the lake, and nearer the marsh than I do, got about as much wild red-raspberry honey as clover, while I got very little, but when clover came our yields were about the same. He got twice as much honey from buckwheat and fall flowers, for my bees had to go too far for it.

A part of our bees are Italian and Carniolan cross; while they look like any hybrids, they are really pure. I think so. We do not want all of the long-tongued Italians, for they will keep on working on red clover after it ceases to be profitable, while the dark bees will be filling up their combs with dark honey from different sources. Yet, if all our bees had been like our best red-clover workers we would have gotten twice the amount of honey we did get, so I think we will do a lot of requeening another summer.

Spraying Trees in Bloom.

I have already reported that the Experiment Station at Geneva, N. Y., counseled against spraying trees while in bloom; that it not only killed the bees, but also affected the delicate organs of the flowers; that in some cases those who had been most active in spraying during blooming-time had found to their sorrow that such spraying had seriously cut down their fruit crops. While these experiments were being conducted at Geneva and in that vicinity, the same kind of experiments were being carried on at Cornell Uni-

versity, N. Y.; and now we have a report from John Craig, of that station, confirming the findings of the General station. This report is published in the American Gardening for April 10th.

It has been urged by the advocates of spraying in bloom, that during seasons like that of 1900, when the trees are heavily loaded with blossoms, spraying at such times has the effect of thinning away the superabundance of fruit. Regarding this, Mr. Craig very pertinently says:

"It seems that, when this admission is made, the strength of the argument is very much weakened. If it is a thinning process, then it could be practiced with safety and advantage only in seasons of heavy bloom." Elsewhere he says, under the head of "Disadvantages of Spraying While in Bloom," that the "researches at Cornell and elsewhere have indicated that the copper salts are very injurious to tender tissues; and that, the more delicate the structure the more likely is injury to ensue. . . . The thinning which follows spraying trees in bloom is probably due to the injury to the pistil or stigmatic surface by the fungicide."

Mr. Craig then mentioned another objection to spraying in bloom; viz., the "destruction of the bees;" and then, in giving a reason why such destruction should not take place, he says:

"When cross-pollination is carried on by the bees, larger fruit will be secured than if self-pollination occurs. . . . Now, if we cover our apple-blossoms with mixtures which are likely to poison the bees, it seems to me that we shall be using against ourselves a doubled-edged weapon."

When it is remembered that these experiments were begun at the Geneva and Cornell stations at the instigation of the fruit-men, who were anxious to prove that spraying during blooming time was an advantage, the results, being just the reverse of what was expected, are all the more valuable.—Editorial in *Gleanings in Bee-Culture*.

CONVENTION NOTICES.

Illinois.—The spring meeting of the eastern division of the Northern Illinois Bee-Keepers' Association will be held at the residence of B. Kennedy, 7 miles southeast of Rockford, Ill., on Rural Route No. 5, and 3 miles northeast of New Milford, Ill., Tuesday, May 21, 1901. All interested in bees are cordially invited to attend.

B. KENNEDY, Sec.

MANUFACTURER OF

BEE-HIVES

Sections, Shipping-Cases—Everything used by bee-keepers. Orders filled promptly. We have the best shipping facilities in the world. You will save money by sending for our Price-List. Address, Minn. Bee-Keepers' Supply Mfg. Co., Nicollet Island, Power Bldg., MINNEAPOLIS, MINN.

Please mention Bee Journal when writing.

ALBINO QUEENS If you want the most beautiful and prolific queens—if you want the gentlest bees—if you want the best honey-gatherers you ever saw, try my Albino Queens in April, \$1.00; Tested, \$1.50. J. D. GIVENS, LISBON, TEX.

CAREER AND CHARACTER OF ABRAHAM LINCOLN.

An address by Joseph Choate, Ambassador to Great Britain, on the career and character of Abraham Lincoln—his early life—his early struggles with the world—his character as developed in the later years of his life and his administration, which placed his name so high on the world's roll of honor and fame, has been published by the Chicago, Milwaukee & St. Paul Railway, and may be had by sending six (6) cents in postage to F. A. Miller, General Passenger Agent, Chicago, Ill. 18A3t

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Apr. 18.—Choice grades of white comb honey sell at 16c, and there is an surplus in sight. Other grades of comb sell fairly well at the following prices: No. 1 grades of white, 14@15c; off grades, 13c; light amber, 12c; dark amber, 10@11c; buckwheat and other dark combs, 9@10c; candied and mixt colors, 7@9c. Extracted is dull, and prices very weak, with the exception of some fancy hinders and clover grades, which is quotable at 7@8c; ambers, 6@7c; dark and buckwheat, 5@6c. Beeswax, 30c. R. A. BURNETT & Co.

BUFFALO, May 2.—Fancy 1 lb. comb, 15@16c; all other grades dragging at 9@12c, as to grade, and not wanted. Extracted not wanted. Fancy beeswax, 27@28c; other proportions lower. BATTENSON & Co.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00. PEYCKE BROS.

DETROIT, Apr. 18.—Fancy white comb, 14@15c; No. 1, 13@14c; dark and amber, 10@12c. Extracted, white, 6@7c; amber and dark, 5@6c. Beeswax, 27@28c. M. H. HUNT & SON.

NEW YORK, March 19.—Our market is virtually bare of comb honey, and there is a fair demand for all grades. Fancy white is still selling readily at from 15@16c; No. 1 white at from 13@14c; amber at from 12@13c; buckwheat, 10@11c, according to quality and style of package. As to extracted, the market is quiet and inactive, and a certain amount will have to be carried over again. Prices are declining somewhat, and if the honey is not moved in large lots, concessions will have to be made. We quote: California white, 7@7½c; light amber, 6½@7c; other grades and Southern, 6@6½c per gallon. Beeswax very firm at 28@28½c, and for exceptionally fine yellow, 29c. HILDEBETH & SEIGLER.

CINCINNATI, Apr. 18.—The demand for comb honey is nearly over. The stock of it also well cleaned up. Fancy white brings 16 cents. Extracted is in fair demand; dark sells for 5½c; better grades bring 6@7½c; fancy white clover from 8½@9c. C. H. W. WEBER.

KANSAS CITY, Apr. 18.—There is very little honey offered, and the demand is steady, selling from \$3.50 @ \$3.80 per case, fancy white; no amber on the market at this time. Extracted, no change; white, from 8@9c; amber, there is a little on this market that could be sold from 7½ @ 8½c. Beeswax scarce and good, at 25@26c. W. R. CROMWELL PRODUCE CO., Successors to C. C. Clemons & Co.

ALBANY, N. Y., May 3.—Honey market very dull. Very little call for anything but choice comb honey, of which there is a scarcity. Extracted quiet. H. R. WRIGHT.

BOSTON, April 4.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15@16c, with a fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8@8½c; light amber, 7½@8c. Beeswax, 27c. BLAKE, SCOTT & LEE.

SAN FRANCISCO, Apr. 17.—White comb 12@13 cents; amber, 9@11c; dark, 6@8 cents. Extracted, white, 6@6½c; light amber, 4½@5c; amber, 4@4½c. Beeswax, 26@27c.

Not much coming forward of any description, and stocks in the hands of dealers are light. The immediate inquiry is not brisk, however, as there are no orders of consequence upon the market, and dealers do not care at present to purchase heavily on their own account.

SOUTH DAKOTA FARMS

Is the title of an illustrated booklet just issued by the Chicago, Milwaukee & St. Paul Railway, descriptive of the country between Aberdeen and the Missouri River, a section heretofore unprovided with railway facilities, but which is now reached by a new line of the Chicago, Milwaukee & St. Paul R'y. Every one contemplating a change of location will be interested in the information contained in it, and a copy may be had by sending a 2-cent stamp to F. A. Miller, General Passenger Agent, Chicago, Ill. 19A3t

The classic in Bee-Culture—Price, \$1.25, by mail.

Beeswax wanted at all times.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

\$15.00 and \$25.00 Queens

Having a Measured Tongue Reach.

The call for queens of our celebrated \$200 imported mother
has been so great that we have decided, in addition to the \$2.00,
\$4.00, and \$6.00 grades of this stock, to offer some \$10.00, \$15.00,
and even \$25.00 of this same blood. But these prices are for tested
queens, the tongues of whose bees have been measured.

The \$10.00 queen is guaranteed to produce bees with a tongue-
measurement of 19-100.

The \$15.00 queen, 20-100.

The \$25.00 queen, 21-100.

These last are very rare and with one exception this (21-100)
is the longest tongue reach yet secured. We reserve the right,
when we do not have the stock with the tongue reach called for,
either to return the money or to send the next lower, remitting
the balance. It would be well for our friends to put in their or-
ders at once, and as soon as we get the grades we will send notice.
When the money is sent, the queens will be forwarded. These
will be put up in the very best manner possible; and while we
guarantee safe arrival in good order to any point in the United
States, on any railway line, we will not guarantee safe intro-
duction. Such valuable queens should be released on hatching
brood.

N. B.—It seems as if it ought not to be necessary to say, that
no one but a queen-breeder or a large honey-producer should order
these high-priced queens; but it is a fact according to our ex-
perience that beginners with only a few colonies will order our high-
est priced imported queens. Such bee-keepers have no more use
for such queens than a pig has for a wheel-barrow.

ERNEST R. ROOT, President.
DR. C. A. KIRK, Vice-President.
R. A. B. MASON, Secretary, Toledo, Ohio.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one (of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

REV. E. T. ARBOTT will soon lecture at the high school in St. Joseph, Mo., on bees and bee-keeping. He knows how to do it in an interesting and profitable manner.

MR. O. O. POFFLETON, of Dade Co., Fla., writing us May 1st, said:

"This season in this locality the honey-flow will be an almost absolute failure, because of lack of saw-palmetto bloom. I hear there is plenty of bloom farther up the coast."

MR. DANIEL DANIELSON, one of the prominent bee-keepers of Turner Co., South Dakota, gave us a call recently. He had been in a Chicago hospital for awhile, and was about to return to his home and farm, where he looks after the bees, not being able to do heavy farm work any more.

MR. M. L. TRESTER, of Nebraska, called on us May 3d. He is not now engaged in bee-keeping, and has not been for years. At one time he was secretary of the Nebraska State Bee-Keepers' Association. Nearly 20 years ago he had a very expensive experience with foul brood. It is an interesting story, as he tells it, though one that he would not like to experience again.

MESSES. BARTLETT BROS. & MERKLY, last year, in one apiary in Utah, from 160 colonies and their increase, took 55,000 pounds of A No. 1 white extracted honey 27½ tons, or a shade more than 343 pounds per colony, spring count.—cleanings in Bee-Culture.

It is no great thing to get 343 pounds of extracted honey from one colony—that has often been beaten. To get that amount from each of 25 or 50 colonies would be remarkable; from 160, spring count, in one apiary—it is stupendous!

MR. WM. M. WHITNEY, of Kankakee Co., Ill., wrote us April 24th as follows:

FRIEND YORK:—I am trying to get caught up on my reading matter, which accumulated during my long absence, and I spend much of my leisure time with the "Old Reliable." While I expected to attend all the sessions of the National Association in Chicago, on account of ill health I was there at the opening session only. I have been very much interested in the report of the proceedings.

On many questions discussed, it is plain, I think, that difference in locality, with different climatic conditions, difference in trade conditions, etc., make all the difference in the world in conclusions—change places and circumstances, and opinions reverse as quickly.

I think you are entirely right in the matter of labeling your honey. If any producer desires to do a retail business, why, it would be all right to label his packages; but it would be presumptuous in me, to wholesale to you, and expect my labels to reach the retail trade or consumer.

I am with the majority respecting the second-hand tin cans. Of the few I purchased two years ago, three were used—two spoiled my honey, and the other was used for refuse drippings. The balance have never been taken from the cases. They were so rusty, and smelt so badly, I dared not use them for any purpose for which I want cans. So I am out the price paid, and \$10 for wasted honey.

I had heard nothing of your removal till the day I called on you at your present loca-

tion; nor did I realize the extent of your misfortune till I read the account in the Bee Journal. You certainly have the sympathy of all your patrons, and it is hoped that what seems a misfortune may prove a blessing in disguise. Your present quarters are certainly much more convenient than the other. I am just lazy enough at my age (73) to prefer riding four or five blocks on street-cars, to climbing two or three flights of stairs, when I wish to find you.

I hope you have not sustained a serious loss.

Truly yours,

WM. M. WHITNEY.

The loss on the stock of bee-keepers' supplies was much larger than we anticipated at the time we settled with the insurance company. We should have had at least twice the amount we received to cover the loss. But, as you say, we believe our patrons will help us out by giving us all the trade they can, and especially try to help us extend the circulation of the old American Bee Journal. For all of which we will be truly grateful, and do our best to give them good value in return.

"BEE-KEEPING BY AN AMATEUR" is the heading of an article in the Bee-Keepers' Review, accompanied by a fine picture of the apiary of the "amateur," Peter N. Duff, of Cook Co., Ill. Beginning less than two years ago, he now has 52 colonies—a pretty good outfit for one who calls himself an amateur. He wintered his bees in a repository above ground—a place generally condemned, but as he succeeded in keeping the temperature between 40 and 45 degrees, he must be excused for successfully wintering. A small oil-heater, with chimney to carry off gases, raised the temperature when too low. Success to the genial Mr. Duff.

MR. GEO. THOMPSON, of Geneva, Ill., we regret very much to learn, died April 14th. He was one of the oldest bee-keepers in northern Illinois, and a very staunch friend of the American Bee Journal and its editor. We feel that his departure is indeed a personal loss, and our sympathy is extended to Mrs. Thompson in her sad bereavement. We understand she has a number of complete volumes of the American Bee Journal, which she, of course, has no use for, and would like to sell. Any of our readers desiring such volumes would do well to write Mrs. Thompson.

THAT STORY ABOUT BEE-TRACKERS in Texas who make a living by marking a single bee as it leaves its hive, then following it mounted on a bronco without ever losing sight of it till it alights on a particular flower, and thus the kind of honey is tracked for each hive—the story is copied in the Southland Queen with the remark that in that part of Texas it isn't the men that track the bees, but the bees that track the men! No doubt the men often "make tracks," and that in rapid succession, too.

MR. CHAS. KOEFTEN reports in the Bee-Keepers' Review that last year, without any help, he took 14,000 pounds of comb honey from six apiaries. Unfortunately the size of the apiaries is not given, nor the yield per colony. If he had 120 colonies averaging 117 pounds each, he must have had little time to waste. If he had 750 colonies averaging 50 pounds each, he must have done some remarkably lively stepping around.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., MAY 16, 1901.

No. 20.

* Editorial. *

Heavy Rains in California the last week in April give almost positive assurance of large crops. It seems that the rains were quite general over the State, and particularly in the central and southern parts. Mr. W. A. Pryal, of Alameda Co., has kindly sent us clippings from local daily newspapers which speak almost gleefully over the hopeful prospects for farmers of the State. This, of course, means much for the bee-keepers as well.

But what if Old California *should* come up to her old-time record as a honey-producing State this year? And if all the rest of the country should also have a large honey crop, this whole nation ought to be well sweetened. And yet, unless there is a proper distribution of the crop of honey, there will be glutted markets and losing prices. There ought to be something done to handle the crop in a manner that will realize to the producers fair and just prices for their honey product. And now is the time to think about this subject—*before* the crop is ready to market, and not *afterward*, when it is too late.

Buckwheat Comb Honey, according to Henry Segelken, of Hildreth & Segelken, in Gleanings in Bee-Culture, is in so much greater demand than extracted buckwheat that it would be well for producers to change from extracted to comb.

Queen-Rearing is discussed by L. Staechelhausen in a very able article in Die Deutsche Bienenzeit. His manner of securing the work of queenless bees seems especially commendable. On one of his strongest colonies (several such colonies may be used) he places an excluder, and over this a hive-body in which he puts four or five frames of brood from other colonies, filling up with empty combs. In eight or nine days nearly all the brood in this upper story will be sealed, and a large number of young bees will have emerged. At this time, in the afternoon, he takes out one of the broodless combs, and moves the frames in this upper story so that a vacant space shall be left in the center, in which a frame may afterward be hung. This upper story is then moved bodily to a new stand. So large a proportion of the bees being young, few will return to the old stand, and in the evening they will show full signs of queenlessness, when the frame with prepared cells is carefully pushed down into the vacant space with full

expectation that prompt work will be started to rear queens, and that they will be found well under way the next morning. This hive, with its contents, can now be returned and placed over the excluder from which it was taken, when the cells will continue to completion.

Editor Pender, of the Australasian Bee-Keeper, makes a practical point by saying that when he takes the frame of prepared cells from the queenless bees (which he says need only two hours to give the cells a good start) he makes sure to take with the frame all the adhering bees, and puts this frame in an upper story over an excluder, between two frames of young brood placed there at least a day before. He says:

I do not disturb the bees on the cups any more than I can help when carrying them to the upper story. I want the work to go on without any check. If I had removed those bees hanging on the frame, and put the frame into the super without any bees, it would be some time before the bees in hive 7 would find the started cells, because the hive is not overcrowded, but by taking the clinging bees, too, the building of the cells goes on as if the change had not been made, and the bees in the super soon assist in making the cells perfect.

Time for Development of a Queen.—In the Australian Bee-Bulletin Mr. Doolittle is credited with saying that from the laying of the egg to emerging from the cell the queen requires 15 days. It is doubtful that Mr. Doolittle would be willing to father that statement, altho there is some good authority for it. In the past 40 years there has been a material shortening of the time taught. In the first volume of this journal, in the year 1861, between 17 and 18 days was given as the right time. At the present day, some say 15, some 16. The 17 to 18 days formerly taught was probably true for a weak nucleus, and 15 may be the normal time for a strong colony.

Shipping Drone-Eggs by Mail.—One difficulty in the way of rearing queens early at the North is that early drones can not be secured. "Swarthmore," in the Rocky Mountain Bee Journal, tells how he has overcome this difficulty. By way of caution it may be said that even if drones were plenty it remains to be proven that good queens can be reared ahead of their usual time. "Swarthmore" says in part:

Last season I was prompted to do some experimenting with drone-eggs, sent to me from many distant points by post, and the result was so highly satisfactory that I hasten to give the long-suffering Northerner the benefit of these experiments.

A number of batches of fresh-laid drone-eggs, in dry comb, were forwarded to me by mail nicely packed in tissue paper and enclosed in 4½ x 1½ section-boxes.

Immediately on receipt of these bits of drone-comb they were fitted into frames and placed in the center of the brood-nest of a strong colony previously made queenless for the occasion.

Very few of these eggs were removed by the bees, and the number of dislodgments in transit was hardly worth mentioning.

The queenless bees readily accept these drone-eggs, and each and every one will be properly cared for, reared and sent forth in handsome, healthy, flying drones long before any other colony in the yard has given a thought to drones or the need of them.

Thus the Northern breeder may gain from six to eight weeks' time in getting under way with his breeding operations for the season, and as soon as the traffic is well understood by both shipper and receiver, I warrant both will wonder why they did not do the simple thing many years ago.

Must Bait Sections be Cleaned in the fall by the bees? A discussion in one of the foreign bee-journals as to whether it was best to put away extracting-combs in the fall without first having them licked out by the bees showed a division of opinion and practice. The claim was made that if the combs were left wet there was danger that the small quantity of comb left would sour. On the other hand, it was urged that giving back the combs in the fall was likely to induce robbing, and that worms were not likely to trouble the wet combs so much as the dry ones. Strangely enough, little or nothing was said about the chief objection urged in this country—the effect of the granules of honey inducing granulation in the fresh honey stored in the cells.

It has been held that the need for fall cleaning by the bees was more urgent in the case of sections than extracting-combs. But G. M. Doolittle comes forward in Gleanings in Bee-Culture and stoutly asserts that it is all a mistake to suppose that honey left in bait-combs will granulate any quicker than it would have done if the sections had been full. He claims as good results by using baits that have not been cleaned out by the bees in the fall. Several others have reported, some on one side and some on the other. So far from agreeing with Mr. Doolittle, Mrs. A. J. Barber reports that even when cleaned out by the bees, her bait-sections are very slow in being sealed. Others say that bait-sections, when properly cleaned out in the fall by the bees and used the following summer are the first to be sealed. A call for more reports is made, and the end is not yet.

"The Wax from the Cappings of a ton of Honey I find to be usually about 25 pounds; when all completely capped, about 30 pounds." So says R. Beuhne, in the Australian Bee-Bulletin.

Convention Proceedings.

Report of the Utah Bee-Keepers' Convention.

The Utah Bee-Keeper's Association held a convention April 5, 1901. The meeting was called to order by Pres. Lovesy promptly at 10 o'clock a.m. Secretary J. B. Fagg called the roll and read the minutes of the previous meeting.

A letter was read by County vice-president C. C. Bartlett, of Uintah County, regretting his inability to attend. He reported the bee-industry in Uintah County in a satisfactory condition; also that there were 50 or more bee-keepers in the county, and about 4,000 colonies of bees. Similar reports were read from County Vice-Presidents A. N. Winsor, of Washington County, W. J. F. McAllister, of Kanab County, and P. M. Grigg, of Wayne County.

Mr. Roberts, one of our old-time bee-keepers, and who was one of the first to introduce bees into Utah, gave some of his early-day experiences in hauling bees many hundred miles on wagons from California. He also spoke on the introduction of the movable frame, on organization among bee-keepers, and on the medicinal qualities of honey.

THE PRESIDENT'S ADDRESS.

I have received fair to flattering reports from nearly all parts of the State during the past 10 to 15 days. The reports from the south, the south central and southeast parts, especially, have been universally encouraging in the prospects for the coming season. I find, as a rule, that the snowfall has been abundant, and it has been more evenly distributed over the State than in other years, thus insuring a fair supply of irrigation water, and so the chances for success are fairly good where the bees are in good condition. But while the many hopeful letters I have received give an encouraging outlook, still the bright picture may have a dark side to it. While the smelter smoke has very much weakened the bees in some localities, still a more serious condition exists in at least one or more counties. I find that there is a great deal of disease among the bees in some places. I have tried to urge a more persistent effort on the part of our bee-keepers to eradicate this disease, realizing that a few minutes spent in prevention are worth a month trying to cure. And one of the many reasons for publishing our expected treatise is that it will benefit our bee-keepers and bee-inspectors by putting into the hands of every bee-keeper simple and effective remedies for the benefit of himself and the industry. Our bee-keepers can and should set a new pace in the new century by helping themselves and aiding the Association in its laudable efforts.

There are other things which we as bee-keepers could improve on to our own benefit and advantage, and one of these is organization. We need no prophet to tell us that our only salvation depends upon a strong union of interest by proper organization. We find that the trades, laborers, farmers, etc., are organizing for mutual benefit, and why should not the bee-keepers? They should organize for the purchase of supplies and also for the disposition of their products.

While many obstacles can be overcome by timely and proper management, still our brightest prospects do not always turn out a shining success, and if we attempt to count our profits by the prospects, we sometimes reap disappointments.

I find the winter question in this State still an unsolved problem; while with proper care the bees can be wintered successfully in most parts, in some places success seems to be almost impossible.

Would it not be well to consider the question of our Association making an exhibit at our State fair, or the one at Buffalo, and also the World's Fair to be held in St. Louis two years hence? We certainly should be represented there.

I would be pleased to have our bee-keepers throw additional light on any of these subjects, or any other one in the interest of the industry, not forgetting the treatise which I wish to publish as soon as possible. E. S. Lovesy.

Vice-President J. Hansen, of Boxelder County, reported the industry prosperous in his locality. J. S. Hamilton, of the same county, reported quite a loss of bees in wintering in his portion of the county, and J. L. P. Johnson, also of Boxelder County, wrote that as a rule conditions were favorable, but that there was some foul brood.

County Vice-Presidents Geo. Hone, of Utah County, A. F. Stevenson, of Davis County, C. O. Falkman, of Weber County, Thos. Belliston, of Juab County, and Ulrich Braymer, of Carbon County, reported their respective counties in fairly good condition. A number of letters were read by the secretary from county vice-presidents, inspectors, and others, and while most of the reports were encouraging, some spoke of loss by disease.

Inspector Anderson, of Cache County, said they had some disease, and that the county commissioners desired him to do all in his power to eradicate it. Mr. Scott reported much disease in some localities, and Mr. Dart exhibited samples of diseased brood, and had a letter read from Dr. Howard, of Fort Worth, Tex., after which a long discussion ensued as to the cause and effect of disease, the best treatment to prevent, cure, etc. The McEvoy treatment, with some modifications, was recommended. Our bee-keepers are waking up, and with the aid of our treatise and our county inspectors, we hope soon to banish it from the State.

A resolution was offered favoring the publication of a treatise or pamphlet by the Association, the object of which is to give the best and quickest method of discovering, curing, and preventing disease among the bees; and also how best to protect them against their enemies. Also, that the State law, the relation of bees to fruit, seed, plants, etc., be published in connection with it. After a long discussion which was participated in by many, the resolution was unanimously passed, and Pres. Lovesy, Secretary Fagg, and Messrs. Thos. Belliston, L. J. Whitney, and E. S. Dart, were appointed a committee to compile and publish the treatise.

Stronger organization among bee-keepers was discussed at length, with no definite results. A resolution was presented and passed, urging the bee-keepers to aid the Association in making an exhibit at the State Fair in October, and also at Buffalo and St. Louis. Many reports were given, coming from honey-consumers in the East, praising the superiority of Utah honey.

The election of officers resulted as follows: President, E. S. Lovesy; 1st Vice-President, R. T. Rhees; 2d Vice-President, Wm. Warham; and Secretary and Treasurer, J. B. Fagg; Assistant Secretary, C. R. Matson. County vice-presidents, Salt Lake, Wm. A. Bills; Utah, George Hone; Wasatch, J. A. Smith; Davis, A. F. Stevenson; Boxelder, J. Hansen; Weber, C. O. Falkman; Juab, Thos. Belliston; Washington, A. N. Winsor; Tooele, Ben Barrows; Cache, Henry Bullock; Morgan, T. R. G. Welch; Uintah, C. C. Bartlett; Emery, Chris Wilcox; Wayne, P. M. Grigg; Carbon, Ulrich Braymer; Sevier, R. A. Lowe; Kane, W. J. F. McAllister.

AFTERNOON SESSION, 2 P.M.

The next question considered was the purchase of supplies and the disposal of bee-products. It was stated that nearly all supplies except sections can be purchased in the home market; and in regard to the disposal of this season's products it was decided to try to keep all bee-keepers informed as to prices, from time to time. The question of grading was discussed at length, and it was shown that a few dealers preferred amber to water white extracted honey because it is cheaper. Still there is a good demand for the best, regardless of the difference in the price.

Mr. Scott urged bee-keepers to be careful in grading their comb honey, because a few partly filled or uncapped sections would not only materially reduce the price of the honey, but it would injure the reputation of the bee-keepers. Mr. Hone stated that, as a rule, the greater portion of the bee-keepers of Utah had a good reputation for fair dealing, but in order to protect their product against any mistakes they ought to stamp their names on each case.

QUESTION-BOX.

Ques.—Is dividing preferable to swarming?

Mr. Hone preferred dividing because he had better success than with swarming. Mr. Whitney obtained very good results by forced swarming. Mr. Lovesy preferred dividing, as the bees are more gentle, the colonies more easily regulated, and better results can be obtained.

Ques.—What style of hive is preferred?

Mr. Fagg—The 10-frame Langstroth for all practical purposes, both for comb and for extracted honey.

Ques.—Does spraying during fruit-bloom kill the bees?

It was proven that it did, and also that it was an injury and no benefit to the fruit-grower.

Ques.—Is winter ventilation necessary?

It was decided that it is.

Mr. Dart—1 put new burlap between the hive and super, with some chaff in it; this keeps the bees dry, and I have no trouble.

J. B. Fagg, Sec.

Bees Dying in the Hives—One of the Causes.

BY C. P. DADANT.

I SEE an inquiry on page 201, concerning the cause of death of a lot of bees. This case seems to me identical to the bee-losses in this vicinity during the winter of 1879-80, and I will ask leave to describe it.

The season of 1879 was very dry. During the summer and fall the bees harvested nothing. But fruits were plentiful and so were birds, and the bees worked during the fruit season on all sorts of damaged fruit. They began on damaged peaches, in August, then took to grapes, and later to apples. The number of bees found in small vineyards was so great that vintners held meetings in which they discussed the advisability of petitioning the Legislature to obtain a law forbidding the keeping of more than 20 colonies of bees in one apiary. Wherever a damaged berry was found it was full of bees and most of the grape-growers were of the opinion that it was the bees that punctured the fruit. Arguments were out of question until the heads became cooler, and it was at that time that we decided to plant grapes on a large scale in order to show our neighbors that grapes and bees could be kept profitably on the same farm, in large numbers and without mutual injury. The damage in this case was really greater on the bees than on the fruit, which had of itself no value for any one, and the bees themselves would have been better off without it. This unwholesome sweet (?) fermented in the hive and became inferior wine, cider, vinegar—yes, mainly vinegar. But there was nothing else for them except an occasional sorghum mill, and sorghum molasses is a poor addition to cider from rotten apples.

We removed all that we could find of this unhealthy food, and fed our bees on the best of sugar syrup. But in spite of it all, we had heavy losses, especially because the bees were confined to the hives for a number of weeks together during the coldest weather. But some people were worse off than we. We bought up an apiary, of some 80 colonies, the following spring. This apiary had been almost entirely destroyed by this bad food during that winter.

Those bees had not been fed, but there seemed to have been enough of this stuff in the cells to keep them till the coldest weather, and there was some of it yet to be found in many of the hives. The bees had slowly dwindled down and had changed position in the hives as the combs had become soiled, until the last small cluster had perished in an upper corner, driven there by the cold and by the stench arising from the foul dead bees. It seems as if a little of this sour food went a great way towards sickening them, for colonies which we had plentifully supplied with healthy food nevertheless showed signs of diarrhea, indicating that they, too, had consumed the nasty stuff.

Strange to say, after the opening of spring, it seemed as if the consumption of this food for breeding was not attended with unpleasant results. Strong colonies that managed to pass through this disastrous winter, prospered and thrived when warm days came, on the plunder that they obtained from deserted hives, for the stuff seemed to be scattered in small patches in many of the combs, the most of it being unsealed, as might be expected.

The most damaging result of this bad food is certainly brought about by the long confinement of the bees during cold weather. In an open winter, when the bees can have a flight once a week, I believe much less trouble would ensue, but when the bees are long confined on the combs, with such watery unhealthy food, they become unable to retain their excrements and the healthy bees catch the infection from the diseased ones. The after result of this trouble in spring is, sometimes, constipation or an inability on the part of the bees to discharge their excrements. This constipation becomes contagious, and in the latter form has been described by Cheshire under the name of "Bacillus Gaytoni." The bees that suffer from it are heavy, they drag themselves about as if partly paralyzed, they shine as if varnished; this comes, I believe, from their having lost all their coat of hairs. Even the queens catch the disease, sometimes, and in such a case the colony is not slow to perish, even if the weather has become

warm. But in most instances the disease slowly disappears or wears out. I have, however, seen it persist through the summer in a few hives and the diseased bees kept themselves almost invariably at the top of the brood-combs, until they were carried out by their merciless sisters, for the bee is pitiless to the useless member of the family, and sickness finds no sympathy with her.

I cannot help thinking that the case mentioned on page 201 is identical with what I have described. The fruit-juice stores, the sickly bees dying in small clusters, the stench in the hives, and the protracted cold weather, all lead to the conclusion that the case is similar, and that we need look to no other cause. By the time this article appears in print, what there may be left of that apiary will probably be in much better condition, as the spring blossoms are a sovereign remedy for Winter's ill-doings.

Hancock Co., Ill.

Numbering Hives and Keeping a Record.

BY C. DAVENPORT.

THERE are some who do not consider it necessary to have hives numbered, but to me it would seem almost impossible to handle a large number of colonies unless the hives were all numbered or distinguished by a letter or figure of some kind. My hives are in rows, and these rows are also numbered, and to have both hives and rows numbered saves a large amount of work, for, as will be explained, it enables me easily to keep track of each colony through the entire season, and, what is of nearly as much importance, I can find or tell where any colony is without searching over the entire yard.

Instead of using a record-book I use smooth pieces of thin boards, which are about four inches wide and 18 inches long. I much prefer these boards to a book or paper of any kind for all transient records, as they are a great deal handier. For permanent records a book is, of course, preferable. With my system it requires about three of these record-boards for a yard containing 150 or more colonies, but each board can be used for a number of seasons, for at the end of the season, if there is anything on them which is desired to be preserved, it can be transferred to a book, and the writing on the boards planed off, when they are ready for use again the next season.

After the bees are put out in the spring, the condition of each colony is set down on one of these boards. A board is marked off into as many rows as there are rows of hives in the yard, and if, for instance, the colony in hive No. 8 in row 5 is weak in bees and short of stores, it is marked on the board under row five thus: 8-M-W-B. The letter M after the number of the hive shows that this hive is in the middle, or about the middle, of the row. I have the rows run east and west, and if it had been nearer the east end of the row than the middle, the first letter would have been E instead of M; or W if nearer the west end.

The first letter after the number always tells where in the row the colony is, and this saves a good deal of walking where there are 25 or more colonies in each row.

The next letter in the record is W, which shows that the colony is weak. Next is the letter B, showing that they are short of stores. If they had had plenty of stores the last letter would have been A instead of B; and if they had been so short that it would be necessary to feed within two or three days, the last letter would have been C.

To explain my system further we will say that under some row we find this record: 98-E-W-A-X. This says that the colony in hive No. 98 is at the east end of that row, and is weak in bees, but has an extra amount of stores. An X after the letter A tells that that colony has an extra-large amount of stores, and in this case, as they are weak in bees, they have more than they can use, so we can draw a frame or two of honey and exchange with and help out No. 8, whose record will now read thus: 8-M-W-B-A. The letter B being crossed shows that this colony has been fed, and the letter A after it shows that they have been fed enough to make them strong in stores. But say we waited a week or ten days before feeding No. 8, and then only fed a small amount, then it would have read: 8-M-W-B-B-4-15. This says that they were fed April 15th enough to last them a week or 10 days from that date. If no honey comes in from the fields by this time, or before, we can tell by looking at this record-board what colonies have to be fed again, what rows they are in, and where in the row.

Later, if it is desired to equalize the colonies in

strength by drawing frames of brood from the strongest and exchanging them with weaker colonies, it is not necessary to spend a day or two in hard work examining each colony, for the record-board shows the strong, medium and weak colonies, and tells just where they are.

Still later, the strong colonies may require more room, especially those that had a large amount of stores—the record shows what and just where these are.

At the beginning of the main flow, or when the supers are put on, another board is taken and a new record begun. This board is marked off in rows to correspond with those in the yard, the same as the first one was. This second record also shows the strength of the colony and where it is. By a system of abbreviations similar to the one I explained in detail, it tells the date when each super is put on and taken off, so that during the flow I can, with this second record, tell about when any colony has a super ready to be removed, or when an empty one needs to be put on. Of course this can not be told accurately, but near enough so that it saves much work inspecting hives which otherwise would be necessary to determine when supers are needed to be taken off or put on.

The third board is used to record swarming. It tells the date when each swarm issues or is made, what hives they are from, and what hives they are bived in. It also shows about how much work, if any, has been done in each super before it is given or removed to a swarm. So at the end of the season these records show what colonies have swarmed, and about what each colony has done in the way of surplus work. Of course, this system of a cipher code or abbreviation in keeping a record of a colony, admits of almost endless variation: for instance, when examining the colonies the first time in the spring, if any are found to be queenless, a small x is placed under their number, and soon after they are united with weak colonies that have a queen, for I have decided that with me it does not pay to try to save a colony that loses its queen during the winter, for after the long winter confinement that bees are here subject to, they live but a short time after being put out in the spring, and, before a queen can be secured from the South and new brood reared, they, as a rule, become so weak that they do not amount to anything that season, so far as surplus is concerned; and with a large number of colonies there is almost always a few that have a queen but are so weak that they are unable to build up in time for the white clover flow. A queenless colony united with one of these may enable them to build up into a strong colony for the white flow, so that anywhere from 50 to 100 pounds of surplus may be obtained, besides artificially swarming or dividing them so as to have, if increase is desired, two colonies in good condition for winter; and this of course may apply to two weak colonies that have queens, for although many have decided that it does not pay to unite weak colonies in the spring, I know that in my locality, under some conditions, it can be very profitably done; but if there is anything about our pursuit that requires skill and experience, it is, in my opinion, uniting weak colonies profitably in the spring.

A Few Grains of Wheat for Honey-Gleaners.

BY ALLEN LATHAM.

It has been so long since I have sent any of my wisdom to the "Old Reliable" that I ought to have a good store accumulated now. So much straw has been sent that I think it is time for a harvest of grain.

BEES AND STRAWBERRIES.

In this locality bees are frequently seen at work on strawberry-bloom in the season of bloom. They appear to get a little honey, but more frequently are gathering scant loads of pollen.

HONEY AND POLLEN ON THE SAME TRIP.

The statement made some months ago that bees do not gather pollen while after honey, must be received by the bee-keepers of Massachusetts with great incredulity. In the season of clover especially do the bees here gather the two simultaneously. In some seasons the sections of clover honey are ruined by the accumulation of pollen in them. We are thankful that this does not happen every year.

APPLE-BLOSSOM HONEY.

I am glad to see that this delicious honey has received its credentials. It is the most reliable honey we have for

quality. With favorable weather a good crop is obtained every year of even date. The trees do not blossom readily on the "off" year with us. The honey is a pale straw color. It is the heaviest honey we get. I have seen it so thick that it was almost gummy. It never candies. It is palatable on the day that it is gathered. This can be said of no other variety with which I am acquainted. I plan to secure a crop every even year by spring feeding. Then on the day that the blossoms are about to open, or perhaps two days earlier, I fill the brood-nest full of syrup. This drives the bees into the sections. To make doubly sure that the bees go up, I put a bait-section, also full of syrup, in the super. This feed does not stay in the section, nor is any carried up. As every bee-keeper knows, the brood-combs get the first of the flow. If the combs are filled with a cheaper feed, then the honey is taken directly to the supers.

This flow from apple-bloom lasts only a few days, usually about 10; hence the necessity of getting the bees into the sections at the very beginning. This treatment will yield some thirty pounds of honey per colony. Some may express fear that the sugar will get into the sections and injure the purity of the honey. This does not happen. The syrup is ripened and placed in the brood-combs. It is difficult to get enough of the thin syrup into the combs to prevent considerable honey going there too. The syrup is poured into the empty cells of each comb from a coffee-pot. It diminishes greatly in bulk in being cured by the bees. It is not desirable to fill the combs more than once, unless a cold rain comes on. Then a small allowance, as soon as clearing weather arrives, will probably drive the bees again to the sections, which they will have drawn away from during the rain. After the crop has been secured the bee-keeper will find beautiful sections of the most delicately flavored honey in the supers. In the corners of the brood-chamber will be found sealed syrup. It does no harm there as it will keep perfectly. I would advise every bee-keeper to run a few colonies for this honey, if for no other reason than to get a choice honey for home consumption. My apple-blossom honey never goes into the general trade. It is all saved for home, friends, and a limited select trade. I sell it always at 25 cents per pound. I never have any last into the second summer.

RUMBLE-BEES IN WINTER.

Possibly the subject has been sufficiently hashed, but I will add my chop. Only the queens live through the winter. They crawl into a pile of leaves and lie inert till April or May. They do not become white, and the writer who found such "about ready to emerge" probably found the imago of the June-bug.

THE TENT FOR MATING OF QUEENS.

This is the best yet. Now let us investigate as to how small this tent can be, successfully. If a drone has never been outside the hive why should he mind small quarters? If a tent six feet in diameter will do, then that is what the small breeder wants. Some of us should hardly care to build a 30-foot one.

TENT FOR BREEDING, ETC.

The "grain" that I shall now offer is worth its weight in gold. Having more honey in brood-combs than I needed, and a great number of unfinished sections, I wished a transfer. I loaded up a strong colony with supers of these sections. Then came the rub. Bees will not empty combs unless they are outside their hive. If outside the combs attract robbers. The problem was solved in this way:

My tent was made of five screens, each six feet square. This tent was placed over the hive with the top removed. Then the uncapped combs were placed within the tent as far from the hive as possible. These bees finished many sections. The work went on all through August. There was no honey in the fields, and robbers were fierce. They would buzz by the score outside the screen, but never go up and in. The home bees quickly learned that to go away from home they must rise, and to return they must get above the hive and drop. This device is of wide application. Every one knows the nuisance of a bee-tent with the bees trying to get out as the hive is left open. With a six-foot fence of mosquito-bar around the hive the advantage of the tent is retained and the worst feature gotten rid of.

If a weak colony is being robbed, try such a fence about it. You will be highly gratified with the result. Robbers will not get in—they will try to enter through the netting, but not otherwise.

BEES IN ATTIC WINDOWS.

I am rather short of land space, and thought I would utilize my attic windows for hives. Two hives were placed facing two windows. A short runway from beneath a window to the entrance served for exit. Two or three small holes were filed through the glass at the top of each pane to let out those bees which left the combs during manipulation. As far as honey-gathering and ease of manipulation are concerned nothing is gained, more than to offset loss. But in wintering much is gained. The two colonies have seen two winters thus. They have come through strong in each. Few bees die, and they all seem unusually vigorous. The combs come through without a spot of mold on them. It is delightful to open hives in which all the combs, even the outer ones, are dry and clean. This means rapid building up in the spring. The two in question are remarkably strong for the season.

I should state that I remove the covers and throw old clothes and papers over the hives for the winter. The attic is unfinished and is well ventilated. The results of this experiment are so pleasing that I shall, at my first opportunity, build a bee-house in which I can set 20 or 30 hives. This would be a tight, double-walled house with double windows. It would have ample ventilating facilities—this for dryness. The bees would get their air by the entrances. An oil-stove would be set in the house on extremely cold nights, for I believe that extreme cold robs the bees of much of their vitality. There would be an arrangement to shade the windows when sunlight would do harm. Such a house would, I believe, save enough in winter stores and in bees to pay the cost of it.

Norfolk Co., Mass., April 7.

Introducing a Queen-Bee—Her Normal Good Graces the Key to Success.

BY W. W. M'NEAL.

I WOULD better, dear reader, impress you with the fact that the honey-bee in all her actions is governed more by *old business principles* than by any feeling of *love* for kin or stranger. I have watched closely the habits of bees for manifestations of love in its true sense, but I am forced to believe that they are swayed by a selfish love only. Her motives may be good; and that from necessity she employs harsh methods. However, it is by her *methods* that we are fitted to judge; and, judging from these we say that her motives are unrelenting.

Let me cite a few prominent traits which characterize the honey-bee as being utterly indifferent to the sufferings of her mother-queen, of her sisters, and of her brothers:

1. If the worker-bees *love* their queen, why will they, when this same queen becomes old and decrepit, allow a young, vigorous queen, and a stranger, to *dispatch the mother-bee right in their midst*? Not only do the workers positively refuse to assist the old and (to them) faithful queen, but when the bloom is on the stranger queen, they welcome her with the keenest relish to the situation she covets. When this same queen has become established in her new home, and is generous to the colony in the performance of her special duties, take her from the bees for a few short hours, or until they realize fully the loss of her. This will portray more clearly their real avaricious, grasping nature, and that *love* with them is an unknown qualification. For when the queen is returned to the bees, note the results: The worker-bees ball her as they would a stranger queen; and in every way evidence a spirit of *revenge* rather than that of rejoicing because she had come back to them. They appear to regard her sudden disappearance as a willful shirking of high responsibility intrusted to her, and, accordingly, the most influential member of the colony is made to feel their indignation.

2. When a worker-bee has given its life in defense of the colony—I mean one mortally wounded, so to speak—and by some means regains the hive before becoming helpless, why is she at once dragged therefrom, *alone to die*?

3. The great, boisterous drone-bee, which was so tenderly cared for when his presence in the hive *guaranteed the safety of the colony*, finally becomes a subject for the worst kinds of cruelty—that of *actual starvation in the midst of plenty; and within the immediate presence of the queen and worker-bees*! If the honey-bees have that quality, or attribute—*love*—which higher intelligences are supposed to have, why do they *always* commit these fearfully cruel acts?

Gentlemen, from my observations of the honey-bees, I am inclined to the belief that it is neither *love* for the mother-queen, nor the peculiar scent of the newcomer, that have to do with the art of introducing a queen-bee. The key to success is in *retaining the normal good graces of the queen*—I might say, the *best* normal perfection, for the honey-bee is the greediest of the greedy, and the question with her is, apparently, *Has the exchange of queens been a good business deal?* Of course, there are exceptions, but this can abundantly be said to be the rule.

Within the waxened walls of the bee's tiny home, individuality is nothing further than to serve the colony in the advancement of its selfish interests. This principle is painfully manifest in all their doings. The stranger bee, whose physical fitness enables it to *help the colony*, is almost always welcomed thereto, until it reaches a period or condition in life which requires that it then be helped by the colony.

Let me call your attention to a few common occurrences in the apiary, which serve to make manifest the assertion that this is the ruling principle with the honey-bees.

1. Note, please, that young bees having just reached the zenith of their physical power and beauty, are, upon returning from a flight, allowed to enter almost any hive they choose. Surely, *these* have not lost their identity—the distinct impress of the queen's scent during the little while they were out of the hive! Oh, no, nothing of the kind. It is seen at once by the older heads within, that *these* are just the kind of helpers most needed, and so they are permitted to join ranks with them.

2. Note, that there is no fighting upon exchanging supers with two or more colonies, when honey is being stored. Why, then, is this? Do not the bees of each colony take with them the peculiar scent of the queen of that particular hive? To be sure they do; but then they always carry with them what is of vastly more importance to the stranger colony—the fact that here is a company of able bees, and ample evidence in the shape of newly built comb and honey, of their *willingness to work*.

3. Note, that at swarming-time there is no fighting when two or more swarms unite; each swarm evidently feels that there is nothing to lose, but lots to be gained, by an addition to their forces.

4. Note, that any colony feeling the need of drones will welcome them to its hive; but when not needing their assistance, it will reject them at once; that a worker-bee laden with honey and pollen may, and quite frequently does, enter the hive of some near-by colony; and that a colony frequently balls its reigning queen when there has been no outside disturbance of the hive.

5. Note, that when the mother-queen, or reigning queen, is found in an unexpected quarter of the hive, she is often stung by the workers; that a colony having a good laying queen will attend upon a score or more of queens in cages, *providing* that these queens have attained their proper or natural development; and that a virgin queen will be allowed to starve to death, her entreaties for food availing nothing. Now, why this partiality? Verily, the virgin is regarded as bringing with her *no security* to the colony, while the queen of the other class, so soon as it is seen that she will not, or can not, molest the reigning queen, is reserved until future use should any accident befall this queen.

6. Please note, also, that the bees of a colony in whose hive there are so many caged queens, are just as able to pick out a robber-bee at the entrance as though there was but the one or reigning queen within. If it is the *scent* of the queen that enables them to exchange their identity, in *what manner* does the queen having the freedom of the hive, so impress upon the bees of her colony her own peculiar scent as to protect them against the depredations of thieving bees?

My bee-keeping friend, I believe that all this matter of the queen's scent is but a vapor cloud, and in due time will have blown away.

I will repeat that the key to success along this line of introducing queen-bees consists in having the queen in the best possible physical condition at the time she is to be given to the colony. She must be the peer of the colony—must be equal to their *expectations*. Not only must the queen evidence an *ability* to do good work, but she must manifest a *willingness* to do the same. Is it not enough to break the even tenor of her ways—the worker-bee's to take away the queen in the prime and beauty of life, and offer instead, a poor, half-starved and frightened little queen to fill the place made vacant?

I have exchanged the queens of two colonies during the

season of surplus, and had each laying in the hive of the other within an hour of her removal. It is done this way: Catch both queens, and then close the hives; smoke each colony a little from the entrance, and then run the queen into the hive from there. The workers having seen that the queen is *eager* to attend upon her special duties, never bother themselves about her incense, but bestow on her every little kindness that was given the old queen. At that choice portion of the season the queen-bees are fullest of life, and neither colony is any the loser; hence there is no cause for dissatisfaction.

Never take a queen from the bees when her duties are imperative, and detain her in any way or manner till she begins to fade, if you wish to give her a chance to run the gauntlet with the most pleasing success.

This is the logical deduction of this matter, drawn from my experience with the honey-bees.

Biographical.

JESSE M. DONALDSON.

On our first page this week is shown Mr. Jesse M. Donaldson, of Franklin Co., Mass., and his nice city apiary. He gives the following account of himself and his bee-keeping experience:

My first lessons in bee-keeping were learned in the early '70's, in the apiary of my uncle, James P. Sterritt, of Mercer Co., Pa. At that time I intended to become a bee-keeper, but, like almost all other boys, I had a desire to travel and see some of the world.

Nature had endowed me with very flexible joints, so I concluded to take advantage of that and become a professional acrobat and contortionist. In that line of business I visited every State in the Union, also Canada, Newfoundland, Mexico and Cuba.

I was married in May, 1886, and a few years afterward decided to quit the show business and "settle down." With that object in view I found employment in the shoe factory where I am now working.

Soon after settling here I became afflicted with that old disease—bee-fever. As it was the second attack, I knew the only remedy, and applied it at once by buying a colony of bees. I saw an advertisement in one of my bee-papers that read something like this:

FOR SALE.—400 colonies of Italian bees in 10-frame Langstroth hives, all in good condition. Price, \$4.00 per colony, on board the cars here. Reason for selling, sickness.

I sent my \$4.00, and in due time received the colony of bees, which I examined as soon as possible. When I saw the inside of that hive I began wondering which it was, the bees or the advertiser that was sick. If that colony was a fair sample of the other 399, it is no wonder that he was sick. Some of the frames were minus an end-bar, others had no bottom-bar, and the whole 10 frames did not contain enough worker-comb to fill six frames.

When I bought my first colony, I intended to keep just enough bees to supply my own table with honey, but I had so many calls for honey that I decided to increase the number of my colonies. I now have 25, but that is not enough to supply my trade, which is growing larger each year.

I have quite often seen this question asked, in the bee-papers: How near to a public highway is it safe to keep bees? If I were to answer that question I should say that much depends upon the strain of bees, and the way they are managed. My apiary, as shown in the picture, is centrally located in a town of 5,000 inhabitants, and not over 50 yards from three streets. When I moved my bees to my present location, many of the neighbors freely expressed their opinion that they would be a nuisance, but up to date I know of but one person being stung. Last Fourth of July morning, a few rowdies wanted the fence back of the apiary to make a bonfire, and while they were tearing it down they struck one of the hives. Then there was trouble. One of the crowd was stung several times. It may seem

very strange when I say that he never entered a complaint against me.

If you will take another look at the picture you will see my two "swarm-catchers" standing at the end of the rear row of hives. They are not the automatic or patented kind, but as swarm-catchers they are a success, because they have not let one swarm get away. If a swarm issues, they are sure to see it; they first notice which hive it came out of, and then there is a race to the shop to see which one will tell me that the bees are swarming.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Detecting Queenlessness in a Box-Hive Colony.

I have a box-hive in which is a large colony of bees. It wintered well, but seems to be at present without a queen. How can I tell that they have none? WISCONSIN.

ANSWER.—Give the bees a little smoke, turn the hive over, blow smoke down between the combs, pulling them apart at the same time, and if they have a queen you will be able to see sealed brood. Another way is to get from a movable-frame hive a piece of young worker-brood and crowd it between two combs so it will be held in place. Two days later if you find no queen-cells started on this brood, you may safely conclude they have a queen. If they are queenless, the bees are very old, and unless quite strong they are not worth a queen.

Dividing to Prevent Swarming.

I have moved 30 colonies of my bees three miles up the creek, right in the midst of hundreds of acres of alfalfa. Now I plan to divide them just as soon as the alfalfa commences to bloom, as I will not be able to watch for the swarms. I wish you would kindly tell me whether I can just put starters of foundation in the brood-frames that I put in, or *must* I have full sheets for fear they will make drone-comb? The way I thought to do was just to take out half of the frames of brood and bees and put them into a new hive, and then fill in the vacant spaces with frames with starters on. Of course I will try to be sure that they have young brood and eggs if I do not know they have a queen.

A year ago last winter I visited at the home of a sister of yours, in Denver, where I learned so many pleasant things about you, and Miss Wilson, too, that I feel quite as if I knew you, and that you will not laugh if I do ask foolish questions; I have nearly 300 colonies of bees to care for the coming summer, and all I know about bees is from reading. I have never even seen a properly conducted apiary, but I have managed to have this many bees with only 5 colonies to start with in 12 years, with only one year's failure, when most of my bees died during the winter and spring. I have very few new swarms of late years—I think it may be because I have so many bees in one place—150 colonies or more. COLORADO.

ANSWER.—If you divide the way you propose, you just must put in full sheets of foundation if you do not want a considerable proportion of drone-comb. I must confess I don't believe that's the best way to divide. It's one of the easiest ways, but not the way for best results. If you leave the queen on the old stand with half the brood, that part ought to do good work, but the other half will have no field-bees at first, and will be in a discouraged condition, which is not the best thing for rearing a young queen. You could use the nucleus plan without making very frequent visits, and have a chance for better queens. Or, here is a way that might suit you, with no nuclei in the case:

Get some good cells started, and when they are within three or four days of having the young queens emerge, make your divisions. Take from a colony all its brood but

one frame, and in this case you may use only starters, and have a fair chance for little drone-comb. That leaves on the old stand the old queen and the field-force, and if the colony is very strong you may risk shaking off a few of the bees into the old hive from the frames you remove. But all the old bees will return to the old stand in a day or two, and it might leave the new colony with hardly enough bees to care for the brood, so it will be safer to take all the adhering bees with the combs you put in the new hive on the new stand. Two days later take the remaining frame of brood from the old colony, and at the same time give to the new colony a sealed queen-cell.

I have a suspicion that you are not anxious for increase from these colonies, but intend to divide them because you know they will swarm if you do not divide. If that is the case, your plan is easy: Just before there is any danger of swarming, remove from its stand a hive and put in its place a hive filled with foundation, putting the queen in this hive, and putting over it a queen-excluder, over which you will place the old hive with its contents. When these two hives are so filled that more room is needed, you can put between the two stories and over the excluder a super either for comb or extracted. With this management you may count on freedom from swarming, unless your experience is exceptional, and you can make your increase nearer home where you can have it directly under your eye. You will readily understand that 21 days after operating there will be no worker-brood in any but the lower story. There may be some drones in the upper story that can not escape, but I have found this trouble more theoretical than real. The remains of the drones will be there the first time you open the hive, and you can easily shake them off the excluder.

Don't you be worried about asking foolish questions. Bless your heart, if you can study up any more foolish things than I have done in the course of my experience you must be an adept in the line of foolishness. The worst of it is that in my case I haven't yet outgrown it, and expect to make more or less blunders as long as I live. I confess to you (but this is only between ourselves) that I do sometimes feel a little impatient when some one asks questions that are plainly answered in every text-book published; but when one has studied the text-books carefully there will still be always plenty of questions to be asked, and with such I am quite willing to be flooded—glad to answer them just so far as I know how. And this suggests to me that you may ask why leave that one frame of brood instead of taking all, and then why take it away later. If the bees are left with larvae entirely bare, they may desert the hive, and if the frame of brood is not taken away within a few days they may prepare to swarm. If you ask why they will swarm if that one frame of brood is left, I may explain that—that is—well, the fact is I don't know.

Gehring's Bee-Veil and Way of Smoking Bees.

I have been reading Mr. Gehring's series of articles now running in the American Bee Journal, but I don't quite like his bee-veil, nor his way of smoking bees before opening a hive. What do you think of them, Doctor?

BUNGHEAD.

ANSWER.—The bee-veil described by Mr. Gehring in his very interesting articles will answer a very good purpose, but is objectionable in one respect—it is made of too close material. When the weather is cool this will matter little, but on a hot day it would be very uncomfortable, and to wear it all day long on such a day would be, I should judge, a rather severe punishment. I wear a veil that has no closer material about it than bobbing or cape-lace, and although that is so open that one might think it would not obstruct the air, yet actual trial shows that it offers decided obstruction, and when I have had one on for some time on a hot day it is a decided relief to get it off.

I doubt whether you would dislike his way of smoking bees before opening a hive, if you were actually to see him at work, for it is not very likely he does just as he says. It is quite common to say that a man preaches better than he practices. This is probably a case in which the practice is better than the preaching, and no doubt writing away from the hive he had not in mind as clearly as he might just what his practice was. Taking it, however, just as it reads, his first act was to blow smoke into the entrance for about 30 seconds, working the bellows with slow, steady pressure so as not to alarm the bees with the noise of quicker motions. Just what is meant by that last I do not fully

understand, for it is hardly possible that any noise made by the smoker can alarm the bees a tenth part as much as the horrible flood of smoke that many of the bees have never before experienced. Indeed, the very object of the smoke is to alarm the bees.

I very much doubt that in actual practice Mr. Gehring blows smoke into the entrance for 30 seconds, first starting "a good volume of smoke." I have just been trying it by the watch, and working the bellows what I considered slowly I made 42 puffs in 30 seconds, and 69 puffs when puffing at the usual rate. That would certainly be an unnecessary amount of smoke, in some cases driving the bees out of the hive, and in any case frightening the bees so much that it would be difficult to find a queen. Then he waited a few minutes for the bees to gorge themselves. A "few minutes" would hardly be understood as less than three minutes. That would leave the bees in good condition to handle, but a practical bee-keeper would hardly feel he could afford to take so much time. If I may be allowed to refer to my own practice, instead of taking $3\frac{1}{2}$ minutes from the first puff in the entrance before opening the hive, I do not take one-sixtieth of that time, for two or three puffs are all that are given, when, without waiting a fraction of a second for the bees to gorge themselves, I immediately open the hive, giving them two, three, or four puffs on top of the frames. That will usually be sufficient, but if at any time they show fight they get more. The humming noise spoken of is a proof of thorough submission; I would hardly consider it one of "satisfaction," but the opposite. Neither would I want to have the bees proceed to much of a humming noise unless I wanted to drive them out.

Using Old Combs—Getting Increase—Italians vs. Blacks.

1. Will the combs of a colony of bees that died with the dysentery do to use again?

2. I have 8 colonies of bees which I wish to increase to 20. Would you advise dividing, or natural swarming?

3. Are the Italians more apt to have dysentery than the blacks? I lost 3 colonies this spring—one being black, and all having the same chance. H. C. A.

ANSWERS.—Yes; scrape off the wood of the frame as clean as you can, and the bees will do the rest. Instead of throwing a swarm into a hive full of such combs, it will be better to get them first cleaned up by the bees, for if they are very filthy a swarm might object to them. Put the hive of combs under a strong colony and oblige the bees to pass through it to get in or out. But if you want that colony to swarm, don't leave the hive under it after swarming-time begins.

2. That's a somewhat difficult question to answer. If you have had little or no experience, perhaps natural swarming would be best. But taking the matter into your own hands will give you fuller control. Possibly a combination might be best. Wait for three or four of the first to swarm, then divide the old colonies into nuclei to be built up from those that have not swarmed.

3. Italians have not had the reputation for being more inclined to diarrhea, or any other disease than blacks. In fact they have been credited, especially in Australia, with being much better to resist foul brood than blacks. Your experience, however, looks as if your blacks resisted diarrhea better than your Italians.

Bees Cross at Swarming-Time.

I purchased 3 colonies of bees in the fall, and the person delivering them put them down in the most convenient place, and I let them alone until I could familiarize myself with them. I came home in the forenoon of April 20th, and found they had swarmed (about a peck measure full), so I had to make a virtue of necessity, and went about it according to the formula in the "ABC of Bee-Culture." I got a hive with full frames of foundation, laid it down on the top of a sheet, got a box and a turkey wing and went to sweeping them into the box (as they were clustered on a tight board fence under the top rail). I got some of them into the box, but it did not take me long to tumble what I had in the box down in front of the hive, and make a very hasty retreat.

Now I take it for granted that there was something wrong with my manipulation, for Mr. Root says that they would be so full of honey that they would not fight, but I need not tell you that I am nursing my wounds yet. I had

a brand new smoker, and got it out, but really did not know what to do with it. I got some rags, lit them, and went back in fear and trembling. I gave them a good smoking, took the same box (with a long-handle this time) and a long-handled brush, and got the bulk of them into the box, dumped them down again in front of the hive, and when they would not go in I smoked them in, and they stayed.

TENNESSEE.

ANSWER.—It is true that when bees swarm they are filled with honey, and are so good-natured that you may have them bare-headed and bare-handed. But it is also true that *sometimes* they are cross enough, just why I don't know. Very likely there was no fault on your part, only you had one of the "sometimes" cases.

Transferring Bees.

Several weeks ago I bought 5 colonies, and found 2 of them very strong, and consequently did not disturb them. Two of them were very weak, so that only one frame could be covered in one, and two frames in the other. It happened that the old home-made frame fit in the new dove-tailed hives which I use, and so I put them into the new hives.

1. Now, would I not better take from them both queens, and unite them into one hive, then give them a new queen? I think the queens are old.

2. Now, the fifth hive was a mess—it was chock-full of honey, and although it was a movable-frame the bees had built their combs diagonally in the frames. I began to cut out from one side where there were no bees, and proceeded until the fifth frame, when I came to the bees, then I lifted the remaining four frames bodily, and put them into a new hive. How can I get those bees out on straight combs? Would you advise leaving them and gradually coaxing them over on new frames filled with foundation?

PENN.

ANSWERS.—1. As your letter is written in April, it is quite possible that a colony very weak at that time may build up to good proportions by the time of the honey harvest. At any rate, it is a common observation that if two colonies that are very weak are in bad condition as to building up, the two united will hardly do any better.

Are you sure about the queens being old? If you are experienced in such matters you may judge somewhat by the appearance of the queens, but even then you may not be sure. If a colony threw out a swarm last year, you may know it has a young queen less than a year old. The swarm will generally have an older queen, although there may be exceptions. Generally, however, the bees will supersede a queen before she is old enough to be worthless. Very likely you will do well to leave the two colonies as they are, unless you want to introduce a new queen for the sake of improving the stock.

2. Yes, fill up the hive with frames filled with foundation, and let the bees work over upon it at their own sweet will.

Weak or Queenless Colony.

I have 2 colonies of bees, and both seemed to winter well, but I notice this morning a great many dead bees in front of one of the hives, and that colony seems weak and not nearly so active and strong as the other. What is the trouble and the remedy?

ALABAMA.

ANSWER.—It may be that there is nothing beyond the fact that the colony is weak. A good many bees die every winter, and some strong colonies will keep them carried away so that you may think that none were lost, while a weaker colony may leave them on the floor of the hive or at the entrance. The chief question is whether there is a good queen in the hive or not. Lift out the frames on which the bees are most thickly clustered, and see whether any brood and eggs are present. If you find nothing of the kind there, they are hopelessly queenless, and the bees left are so old that they are not worth fussing with. There is a bare chance, however, that they have reared a young queen that has not begun laying yet. In that case you may find no brood except a little sealed brood. If you want to make sure of it, give them a frame of young brood from the other colony, and if they start queen-cells on it you may believe them queenless; but if no queen-cells are started in two or three days, there is still hope they may have a queen. If they start cells, and they are sufficiently strong in bees,

you may allow them to mature the queen-cell, but the game is not likely to be worth the candle. If you find the sealed brood in worker-cells raised like little bullets instead of being flat, you may know they have a drone-laying queen or laying-workers, in which case the only thing is to break them up.

The Commonplace.

"A commonplace life," we say, and we sigh;

But why should we sigh as we say?

'Tis the commonplace sun in the commonplace sky

Makes up this commonplace day;

And the moon and the stars are commonplace things,

And the flower that blooms, and the bird that sings;

But dark were our fate, and sad were our lot,

If the flowers should fade and the birds sang not;

And God, who watches each separate soul,

Out of commonplace things makes this beautiful whole.

—Selected.

"DAD BUTTER"—HOME COURTESIES.

This would seem a curious text for our greeting to "The Home Circle" friends. Yet it suggests some valuable thoughts, as we shall see.

I taught my first school when I was young—in my teens. How vivid are some of the things of our childhood and youth! How stamped upon memory was the ride—11 miles—with my dear old father, as I went to try my skill at the teacher's desk. Among other wise things my father said was, "Start right." That might well be a text for any epistle or sermon. Again, "Never lose your self-control." A man near Claremont was shot yesterday—another man lost his self-control. The one will be marred through life, if not worse. The other will doubtless languish for months behind prison doors, and will have long, bitter, regretful thoughts. Did I say too much in a previous article? Can we say too much to our dear children at the very first, from cradle up, regarding the importance of self-control? I am glad my father impressed it upon me on that memorable ride, as I went to fashion the still younger lives.

Again, my father said, "Never be called in the morning." I was to "board around," and such evidence of energy he thought would win me favor. I think I was never called, and I was often first up, and in the quiet of those early hours I not only carefully read my New York Tribune (which was a good school for a school-teacher), but also read during the winter Irving's "Life of Washington." Whatever some may think of this advice, its results were certainly good in my case.

Again, father urged that I use no words that I would not use in the presence of the most refined ladies. This was good advice. I hope I followed it. Were I to train children to-day—were I to bring up my children again—I would start urging the "yea, yea," and "nay, nay," which the blessed Master enjoined upon all his disciples. There is something so sweet, wholesome, and impressive in the pure, direct speech, especially in these days of slang, that I wonder more are not enamored of it.

But why my text? I often noticed as I boarded with the good people, that the language of the children was not always courteous, respectful, refined. The people were for the most part—indeed, almost in their entirety—thoroughly good people; people who would sacrifice heavily to aid a neighbor who might need comfort or assistance; people who prided themselves upon their honesty; whose word was honored in matters of common report or in business. It was a neighborhood that would soon empty itself in case the country should be threatened and assistance required. This was proved two or three years later, when the call for 100,000 men was sounded by that glorious man who then guided the great "Ship of State." It was a goodly folk to meet, and I used my opportunity and dwelt among them poor and rich alike. No home escaped my visitation. I have rejoiced ever since that the poorest and least respected

were not omitted in my visitations and sojourns. It is good to see how the other folks live. It is good to share with them their crusts, and break doughnuts with them in good-fellowship. I wish all our Carnegies, Vanderbilts, etc., could have taught school and have "boarded around" in the early, impressive years of their lives. It would certainly have awakened in them a real heart-sympathy for the hosts of poor people that would later be associated with them.

As I sat in all these homes, about the evening candle—those were still the candle days in the country homes: or, as we enjoyed the evening meal, or sat at the early breakfast, served usually by candle-light, and usually before six o'clock, I had good opportunity to study manners, and to note the words and address of my pupils in the close intimacies of their homes.

One morning, in my opening talk at the school, I essayed to inspire the pupils with more deference and courtesy in their associations with each other, and especially in the home. I was quite specific in urging them to politeness in the home, and at that best of places—about the home-table. I thought they seemed impressed, and that my examples of proper and improper address and phrase would sink deeply in their memories, and bear fruit in a better habit and manners in the homes and about the home meals.

That night we had hardly taken our seats at the supper-table, before one of the boys, in a large family of children, piped out in emphatic tones—"Dad butter!" I wondered if all my good advice and suggestions had taken as shallow root as in this case.

A lady said to me a few days ago, "How can we keep our children from slang?" I rejoice that mothers wish to. A flower, a mountain, a woodland, not only pleases the eye, it elevates the taste, and purifies the life. Ugly sights influence in just the reverse way. Happy the child who is only familiar with beautiful scenes, and lovely pictures of life and environment. Words are like pictures, they make or mar the taste, refinement, and the life. I have so often blessed God that I never heard a profane word, a vulgar phrase, and hardly a byword from my father's lips. I have three children; I think their language is so clean and pure that it would grace any company, and would never be criticised.

We parents wish so earnestly that our children should use only good words. We have the matter largely, if not entirely, in our own hands. First and best, we must be "living epistles." If we occupy the place every parent ought to hold in the minds and hearts of our loved ones, what we say, or do not say, will tell tremendously to fix their habits of speech. Example is our best weapon in this warfare.

Again, we must so interest ourselves in our children—be so one with them that our advice will always tell. Let us advise that bywords and slang, sarcasm and abrupt and discourteous phrases, be never heard in the home, or used by the children. "Dad butter" may get the unctuous solid, but I am sure it will not taste as good as if it came with, "Father, will you please pass the butter?" Home courtesy, and everything that makes toward it, is a rich adornment in every household.

When I left home for college my blessed mother said to me—her arms encircled my neck, her tears enriched the words, and a blessed kiss was her seal—"I am glad to know that no word, phrase or story will you utter that you would not be willing that your mother should hear." I am so glad my mother said it. I believe my college life did not disappoint her. How I rejoice that it did not.

To paraphrase: "A word fitly spoken is like apples of gold in pictures of silver." I hope none of our "home circles" will be marred by any other.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

The Premiums offered this week are well worth working for. Look at them.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

THE UNCAPPING FORK.

If the implement known as the uncapping fork has been in use 20 years, and has occupied all that time in getting itself heard of on this side of the world—well, one would say it can hardly be of very great value. Perhaps that's not the way to look at things, however. At any rate the slowness of truth when chasing a popular falsehood seems to have found its match. This is about those pictures furnished by Mr. Griener, on page 215. All tools for uncapping, one would say, which operate like a garden-rake, and draw all they get hold of in front of them, must manifestly be self-clogging and too slow for general business.

THE UNCAPPING ROLLER.

How about that roller full of fine prickers to puncture the cappings instead of removing them? Can it be depended on to let go of the cappings? The prickers must be near together else some of the cells will be missed; and if near together will it not, first you know, pull off small patches of capping and hold on to them until its operation is clogged? I have a little pricking arrangement not a roller which departs itself in about that style; and picking things clear is an undurable waste of time. Perhaps a rolling motion instead of a patting motion would obviate that, like whole or in part. I fear, however, that the uncapping roller is one of the Galatians—"run well for a time"—and short time at that. It is by no means absolutely necessary that an uncapping device should remove the cappings at all. It's nice to have that done; but if the new device works rapidly enough, and well enough, we can afford to float out the cappings with the inverted syphon, or lift them off the gravity tank. There is another thing to be thought of, however. If we give back most of the cappings to the bees in a ragged condition they may take a notion to throw away the most of them, to our serious loss.

MR. CHAPMAN'S METHODS AND MANAGEMENT.

The long article of S. D. Chapman, pages 215-217, very valuable as it is, needs lots of discrimination on the part of the reader. Things which will work in one locality will not work in another; and a series of two or three operations may work well when the most captivating member of the series, torn out and used alone, might be ruinous. Or, again, take the plan of killing all queens early in July—the man who *overworks his queens* so that they need killing has a great deal more occasion to follow that plan than the man does whose bees run their brood-rearing according to their own sweet will—albeit there are some other reasons not directly connected with premature old age.

The idea that queens will lay much faster in the middle of the brood-nest than in outside combs will come to some of us as rather a novel one. It is quite likely to be correct; and if correct it is a large-sized item to conjure with.

Another prominent idea is not exactly new, but one which many of us have entertained (perhaps a little sheepishly or elandstein-ly) that the time spent on very weak colonies in spring is time thrown away.

I note that he does not claim for his diligent taking out of brood and putting in of empty combs at, but only puts it 40 percent to the good. It is of value to have the experience of an expert that a dozen queens hatching in an upper story do not necessarily make the colony swarm. I believe it has been said that running the same colony for both section-honey and extracted is a practice poor if not uneconomical. Here we have a forcible and plump denial at strong hands—more bees, and more comb-honey, and some extracted honey as a sort of free gratis.

Raspberry bloom and berries in all stages in northern Michigan up to November 1st, is simply another of the many evidences that last autumn was a very abnormal one indeed.

That out of 110 colonies 80 should neglect to start cells when queens were killed, until brood was all too old, is a very strange experience. Good case to bear in mind as evidence that "one can't pretty much always tell" what bees will do, or what they will not do.

QUEENS!

Improved Golden and Leather-colored Italians are what **H. G. QUIRIN** rears.

We have one of Root's best long-tongued Red-Clover Breeders from their 23rd queen, and a Golden Breeder from Doolittle who says if there is a **BREEDER** of golden bees in the U.S. worth \$100, this one is worth that sum. The above breeders have been added to our already improved strain of queens for the coming season.

J. L. Gandy, of Humboldt, Neb., wrote us on Aug. 5th, 1900, saying that the colony having one of our queens had already stored over 400 pounds of honey, mostly comb; he states that he is certain that our bees work on Red Clover, as they were the only kind in his locality and apiary.

A. L. Root's folks say that our queens are extra fine, while the editor of the American Bee Journal tells us that he has good reports from our queens from time to time. We have files upon files of unsolicited testimonials.

After considering the above evidence, need you wonder why our orders have increased each year? Give us a trial order and be pleased. We have years of experience in mailing and rearing queens. Safe delivery will be guaranteed, and instructions for introducing sent with each lot of queens.

QUEENS NOW READY TO MAIL.

BULL-STRONG!

...PIG-TIGHT...

An Illinois farmer said that after harvest he had fully 300 bushels of loose oats on the ground that he could not securely prevent from being lost, because the fence around the field would not turn dogs. Figure the loss for yourself. He also said, all this would have been saved if he had used the Kittleman Woven Wire Coiled Spring Fence, and the value would have been a long way towards paying cost of the fence, with the **Duplex Machine** any farmer could have made it at the actual cost of the wire. Catalogue free for the asking.

CAREER AND CHARACTER OF ABRAHAM LINCOLN.

An address by Joseph Choate, Ambassador to Great Britain, on the career and character of Abraham Lincoln in his early life—his early struggles with the world—his character as developed in the later years of his life and his administration, which placed his name so high on the world's roll of honor and fame, has been published by the Chicago, Milwaukee & St. Paul Railway, and may be had by sending six (6) cents in postage to F. A. Miller, General Passenger Agent, Chicago, Ill. 18A3t

Bees Beginning the Season Well.

We are having an early spring in this part of the State, and a good one, too, with the exception of a little north wind.

I have some colonies that are already filling their second super with comb honey this season.

W. T. FRANCIS,
Sutter Co., Calif., April 14.

Wintered on Granulated Sugar.

Mr. Gill, a bee-keeper here, put a colony on nothing but granulated sugar in the fall, and they wintered as well as those with an abundance of stores of honey. Another neighbor "took up" his bees, and Mr. Gill simply shook them on dry comb into another hive, set it in the same place, and put on a Miller feeder containing 15 pounds of sugar. The season here is fairly early.

J. PROCTOR OTIS,
Quebec, Canada, April 24.

Cold and Misty New England.

We have had hard weather for bees. April has allowed only three days for pollen-gathering thus far. Mist and rain have been the prevailing things in New England. The consequence is, that bees have alternately started brood-rearing then ceased. The patches of brood are very ragged. Ten days of cold, misty weather at a stretch will put a dead-stop to brood-rearing. ALLEN LATHAM,
Norfolk Co., Mass., April 28.

A Cloudy, Rainy April.

Bees have had a hard time—only 22 hours of sunshine in 26 days in April. On all other days it rained hard. No doubt good results will come from this soaking, as this part of the globe had not been wet down for three years. Wells were dry, springs were low, and now the wells and springs are full—also a good many cellars.

Bees are doing well now, carrying in pollen. HENRY ALLEY,
Essex Co., Mass., May 1.

Experience in Growing Cleome.

On page 244 the editor asks for information concerning cleome. I raised last year in our garden, where the soil is dry rather than wet, but of course it was watered every day. It grew so thriftily that one so inexperienced as I might suppose it would grow almost anywhere. My garden had only the spade to loosen the soil as a preparation, and the seed was planted near the first of May. It grew quickly, and transplanted kindly when about 3 inches tall. The plants should be set at least three feet apart as it branches extensively, and every branch flowers. Mine grew from 3 to 5 feet or more tall, as I remember them. The leaves resemble the leaves of the horse-chestnut, and many are quite as large. The plant is slightly thorny and somewhat aromatic, emitting a sweet juice, or dew, in perceptible but almost infinitesimal drops. It began flowering the last of July, growing from what appeared to be an umbel of buds into a spike of flowers; the showy spike lengthening and blooming until cut off by the frost. Strange to say, every flower in the garden succumbed to the frost before it did, so that it was not only a "thing of beauty," but of interest, because I had supposed it to be a semi-tropical plant. The flowers are very odd, the long stamens growing on one side of the four petals; the seed-pods are very long, growing on long stems, and these clothe the spike while the upper part is in the bud and in full flower. Perhaps these give the plant the name it sometimes bears, that is, "the spider-plant."

It grew so easily for me in my first attempt at gardening that I think if I had a farm, or

Tennessee Queens!

Fine lot of Choice Tested Queens reared last season, daughters of select imported and select golden queens, reared 3½ miles apart, and mated to selected drones, \$1.50 each; untested warranted Queens, from same breeders, either strain, 75c each. No bees owned nearer than 2½ miles. None imported within 3, and but few within 5 miles. 2½ years' experience. Discount on large orders. Contracts with dealers a specialty. JOHN M. DAVIS,

Standard Belgian Hare Book!

BY M. D. CAPES.

THIS book of 175 pages presents a clear and concise treatment of the Belgian Hare industry; its growth, origin and kinds; the sanitation and care of the rabbit; selection of breeding stock; care of the young, feeding, diseases and their cures, scoring, marketing, shipping, &c. First edition of 50,000 copies was sold in advance of publication.

Price, in handsome paper cover, 25 cents, postpaid; or with the American Bee Journal one year—for only \$1.00.

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

large piece of land, I would loosen up the soil, and set a plant here and there in the pasture, and even by the roadside, and should expect it to grow, because some of the plants I set out were in rather poor soil a little sandy—and not out of the soil to grow.

I might add that during the first of the blooming I did not find the bees very frequent visitors, seldom seeing any, but at the last of the season they seemed to appreciate it, perhaps because most other flowers were gone.

It said it was watched every day, but I am mistaken about that, although I found that the plant did not resent the neglect.

Bees Expelling Water from Nectar—Fruit-Bloom Honey.

Prof. Cook says on page 149, in his "Review of A B C of Bee-Culture."

"I have always wondered at the statements we so frequently see of bees expelling water from the honey while on the wing. I never saw it, and I don't believe they do it," etc.

I was indeed surprised to read this from Prof. Cook. I have seen bees expel water from the honey as they left buckwheat fields for the hives, and I think all doubt will be removed from the minds of those who do not believe it if they will get bees to work on a piece of comb containing honey as bee-hunters do it. Then have some honey so diluted with water that it will be only sweetened water, but sweet enough so that the bees will work on it readily. Now put some of this into an empty comb, remove the original comb, and place the watered honey in its place. Watch these bees as they fill themselves from this and circle around before they take the "bee-line" for home, and I think if your eyesight is good you will no longer doubt that they expel water, and it is not always a very "fine mist," either.

I have used very thin syrup when hunting bees, for nearly 25 years, as I found by repeated experiments that a bee would fill itself to its untoward capacity, and then after expelling a quantity of the load in the form of water (soon after leaving the box, and always before she got out of sight), make the trip of one or two miles, and return in much less time than when a thick syrup of honey was used for bait. All good bee-hunters know this.

On the same page Prof. Cook speaks of Mr. Root being in error about fruit-bloom honey. I think Mr. Cary called Mr. Root's attention to this, and he acknowledged his mistake. I have seen hundreds of pounds of pure apple-blossom honey at the apiary of Mr. Cary, and have had a few cases of comb honey gathered from it by my own bees. With the exception of raspberry honey it is the finest we have.

Worcester Co., Mass. JAMES F. WOOD.

Three Hive-Bodies Per Colony for Extracted Honey.

On page 137 I read the questions on ventilating supers, and then I read Dr. Miller's replies, and was very glad to find that I was walking to some extent in the footsteps of such a great bee-keeper as Adam Grimm. I ran entirely for the extracted honey, and for every colony I use three s-frame dovetailed hive-bodies and one super. I winter them on the summer stands in two hive-bodies each, and in the spring I feed so as to cause all to swarm once and no more. The parent colony is left all summer by the old stand, and facing at right angles to it, and when it is required I place a super on it, but as soon as a swarm issues I put a ventilator under the old colony, about 1 1/2 inches deep, opened along both sides, but covered with wire-cloth. Then I hive the swarm, which is generally very large, and under that I put a ventilator 3 inches deep, about three days after they swarm. I extend the parent colony, and give it eight of the frames that are nearest to being hatched out, and put it on top of the new colony with a honey-board between and another ventilator on top 1 1/2 inches deep. So

Depot: Van Buren St. and Pacific Av., Chicago, on Elevated Loop. No. 8—20A2t

you see there is plenty of ventilation, but in case of a stoppage of the honey-flow I am not afraid of robbers.

My principal reasons for using three hive-bodies to the colony are as follows: First, I can renew my queens at will. As soon as the season is over, and I put them away for winter, if the parent colony has a prolific young queen I put the parent colony on top of the swarm, first killing the old queen.

Second, I depend upon the parent colony to put away some honey for winter stores for both outfits, as I find as a rule that the swarms do not store enough to winter on—just a little strip along the top of each comb in the bottom story.

Third, by this method of doubling up every fall I have the same number year after year, and do not have so many combs to protect from bee-moths.

We have had a very mild winter, and bees have flown at least one day in every week, and now I have them busily engaged in carrying artificial pollen to the hives. I use from one to five pounds of flour a day mixed with flaked oatmeal, and they visit it by the thousands. I don't expect to get any honey, but I should beat the 1100 of the bees in the apple-tree bloom." At night I feed a quart of syrup made from 30 pounds of the best granulated sugar, 40 pounds of water, and 15 pounds of honey. I think fruit-bloom will start next week, then my work will be over for awhile.

W. H. ALDER.

Callahan Co., Tex., March 4.

More Rain in California.

It began to rain last night, and up to the present time (8 p.m.) it has rained three-fourths of an inch. This is the first rain in the San Gabriel Valley since Feb. 7th.

J. T. HADDOCKS.

Los Angeles Co., Calif., April 30.

Worst Spring for Years.

My bees came through the winter seemingly strong, but when closed up in the fall, they brought in pollen and honey April 4th—four days earlier than last year. Then we had a cold, wet time, killing all the early blossoms, for two weeks or more, and the bees had a hard time to live, as they had a quantity of brood—in fact, it has been the worst spring for bees we have had in years. The past few days everything has been coming rapidly forward, and the trees are in bloom, yet there is a lack of moisture, and there seems to be no nectar in the blossoms. I have made a few improvements or discoveries during the past season, and will write about them later. D. H. METCALF.

Calhoun Co., Mich., May 4.

Report from the "Old Dominion."

I began the season of 1900 with 47 colonies, spring count, and increased to 52, working on Doolittle's plan of spreading brood. I met with perfect success in using that plan, securing populous colonies which were in readiness when the honey-flow came. We destroyed all drone-comb in colonies we did not wish to rear from, selecting from colonies with the best and brightest drone-breeders, and also selecting from colonies with the best layers and honey-gatherers to rear queens from.

Our honey season was tolerably good during the months of June and July, when our bees gathered the most surplus. During August and September the bees did not do much, but the latter part of September and the first of October they laid in a good supply for winter stores from wild aster and gold-rod, and some surplus from smartweed.

We tried the Golden plan on one colony, and found it a complete success. We shall adopt it to some extent during this season. We want to increase to 65 or 75 colonies.

Our bees come through the winter all right with the exception of a few that were careless, and we have 48 colonies now. During the month of February the weather was very mild and pleasant, but it doesn't look now as if we were going to have much of a honey season, as the snow is flying in all directions,

and the mountains around about us are clad in mantles of snow.

Our crop last season amounted to over 3,000 pounds of comb honey—we do not extract any, which we consider pretty good for the season, as there was a drought which cut our corn crop short by over one-half.

P. I. HUFFMAN.

Rockbridge Co., Va., April 22.

Clipping Queens' Wings.

G. M. Doolittle enumerates the advantages in the American Bee-keeper, viz.: Greater ease of finding a clipped queen in a hive; security against runaway swarms; freedom from climbing trees or getting swarms from difficult places. Either one of which might be sufficient reason for the practice.

Queens Flating in the Hive.

This is reported in Gleanings in Bee-Culture by H. L. Jeffrey as a success, but Editor Root thinks there may be some mistake about it.

A Swarming-Stick.

For those who depend upon having their bees settle so as to hive them, it is by no means a pleasant thing to have the cluster on a very high tree, or in the middle of some thorny shrub, tree, or hedge. Mr. J. F. Munday has this to say about a "swarming-stick" which he uses:

It is therefore advisable for a bee-keeper to prepare suitable places near his apiary for his swarms to settle on. The plan I adopted was the following: I bored an angle-hole in the top rail of the fence which enclosed my apiary. I then got a stick about two feet long, one end of which would slip into the hole made in the rail; on the other end of the stick I fastened a small bag of dry grass about the size of a small pumpkin. Before making the bag, I placed the material of which it was made in a piece of the fence on the top of the frame of a hive of bees for a few days, to obtain the scent of the bees on it. Well, I simply placed this stick with the little bag of grass on it in the hole made in the rail of the fence, and I had the satisfaction of seeing my swarms settle on it, or rather them, for I had four of them in different places.

Now, I do not wish to imply that all my swarms settled on these prepared places, for they did not, but the majority of them did, and when they did, after placing a hive ready for their reception, I gently removed the stick with the swarm on it from the hole in the rail and carried it to the hive. With another little stick I carried, or with my hands if I had not got one, I detached a few bees from the cluster, letting them fall at the mouth of the hive, and when I noticed them entering the hive satisfactorily I shook off the rest of the swarm, and when most of the bees had entered the hive I returned the swarm-stick to its place in the fence again.

Foul Brood An Important Subject.

Every little while there comes a frantic inquiry from some bee-keeper to know what is the matter with his bees, and what he shall do for them. He suspects the presence of foul brood, but is in utter ignorance as to what the symptoms are. Heretofore he has seen much about foul brood, but has always skipped it in his reading—let those troubled with the disease trouble themselves with the reading. The wise bee-keeper will not wait till he is per-

DR. A. E. MASON, Secretary, Toledo, Ohio.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

☞ If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seeker to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

DR. PEIRO has removed to 78 State Street, Chicago, opposite Marshall Field's, where he would be pleased to see friends of the American Bee Journal at any time when they are in the city.

G. M. DOOLITTLE "gets off" the following in one of his editorials in the Progressive Bee-keeper for May:

PACKING POLLEN.—An amateur bee-keeper once told how this was done, in these words: "When a bee brings pollen into the hive, she advances to the cell into which it is to be deposited, and kicks it off; another bee, one of the indoor hives, comes along and rams it down with her head and packs it into the cell as the dairymaid packs butter into a firkin. The paper publishing, said, 'We prefer not to have any dairymaid pack our butter that way.' Another paper seeing both of the above, remarked, 'If our butter must be packed in that way, let it be done by a bald-headed dairymaid.' Still another paper, after reading all the above, ventured, 'We will add that in either case it would be dand-ruff' on the butter.'"

DAFT CITY FATHERS.—The Daily Camera, of Boulder, Colo., for May 4th, contained this paragraph which is of interest to bee-keepers:

"Our neighbor, Longmont, is beginning to feel quite metropolitan. She has passed an ordinance to keep cows off the main street and now tackles the bee-question. Hereafter no person shall be allowed to keep more than 4 colonies of bees in the corporate limits. This ordinance has caused a humming and buzzing beside which the noise of the bees was as nothing. The matrons and farmers of the town are up in arms, and really it does look as if the town council is putting on unwelcome airs. Why banish the busy bee and the luscious honey?"

It must be that Longmont rulers think their bee-keepers are enjoying a bonanza, and that they must do what they can to keep them down, or drive them out. Instead of trying to encourage an honest and honorable industry there seem to be people who would prefer to destroy it entirely. But we can hardly believe that a majority of the residents of Longmont will permit such an imposition upon their bee-keepers as the one suggested in the foregoing quotation.

MR. MACKENZIE, THE PROPOLIS MAN.—Those who attended the National Convention at Chicago last August will recall the discussion of the question as to the practical use of propolis, or whether it has any commercial value. A man by the name of John MacKenzie, of Troy, N. Y., was present with samples of leather and furniture polish, in which propolis was a prominent ingredient. We believe he offered to pay 50 cents per pound for propolis, saying that he expected to be able to use it in large quantities.

It seems that Mr. A. G. Wilson, of Vernon Co., Wis., sold Mr. MacKenzie a quantity of propolis, but has been unable to secure payment for same. He wrote us during the winter about it, asking us to do what we could to help him get what Mr. MacKenzie owed him for the propolis. We wrote the Troy man, but received no reply. A few weeks ago Mr. Wilson again wrote us, when we again wrote

MacKenzie, saying that if we did not hear from him within two weeks we would mention the matter in the American Bee Journal. We are now simply keeping our promise to him.

Mr. Wilson, writing us May 8th, gives the following facts:

FRIEND YORK:

On or about Nov. 1, 1900, I sold and shipped to John MacKenzie, of Troy, N. Y., 65 pounds of propolis at 25 cents per pound. After waiting a reasonable time for settlement, I wrote and reminded him of the shipment and the amount due me, to which he made no reply. I then drew on him through the bank, and you will see the results (dishonored drafts, etc., are enclosed). I have not heard from him in any way since I shipped the propolis to him. The propolis was sold through a sample sent to him, he agreeing to pay for it as soon as it arrived in Troy. These are the facts in the case. Yours truly,

A. G. WILSON.

We do not know whether there are any other bee-keepers who have been so unfortunate as to have shipped any propolis to MacKenzie. We trust not. We were hoping that Mr. MacKenzie was all right, and that he really had found a good use for propolis, as we were aware that certain bee-keepers would be able to supply it in fair quantities.

If our memory serves us rightly, Mr. Frank Benton also met Mr. MacKenzie, and told him he had about 40 pounds of propolis saved up, which he would ship to him. We think Mr. MacKenzie asked him to ship it C. O. D. We have since wondered whether Mr. Benton sent his stock of propolis to him; and if so, whether he received anything in return for it.

MR. J. C. ARMSTRONG, of Marshall Co., Iowa, when renewing his subscription recently, had this to say about some so-called bee-keepers:

"I have delayed renewing some time, thinking to get a couple of subscribers to whom I sold bees, but they are not ready. They want to wait until they get their money's worth out of the bees. Last spring I sold a colony to a man and asked him to take the American Bee Journal and a book on bee-management, but he said, 'No, I will wait till I see what luck I have.' I told him if he had good luck he didn't need a book, but the way to have luck was to read up. I saw him occasionally through the summer and he was having good luck. He had gotten two swarms! I have not heard from him this spring, but I suppose he will sing a different song now—no luck. That is the way with them. They will commence at the wrong end of the business. If a farmer were to go to work on his farm with no more knowledge of the business than they have of bee-management, and trust to luck, we would think him foolish. Yet they are wise!"

A "MEASLEY" EDITOR is Mr. H. E. Hill, of the American Bee-keeper. If we may take the following paragraph in his May number to refer to himself instead of to a youthful member of his family:

"It is our rare privilege this month to have a case of measles against which to charge any editorial short-comings."

That reminds us of the exceedingly "measley" time we had when the measles struck us. We were 21 years of age, and as is well known when this disease takes hold of an adult, he is liable to have a hard time of it. We were attending college at the time, so away from home and mother. We will never forget those days, and how when mother arrived the sick boy began to mend almost at once. Ah, can any one ever forget a mother's love and tender care? God bless all the dear, self-sacrificing mothers—yes, and all the boys who are away from home and mother.

City Ordinances Against Bee-Keeping.—We have received newspaper clippings from the Rochester, N. Y., daily papers, announcing that an ordinance relating to the keeping of bees within the city limits was passed there by the common council April 28th, to go into effect May 2d. It provides that no bees can be kept within the city limits without the written permission of lot-owners within 100 feet of the hives; such written permission to be filed in the office of the city clerk.

The passage of the ordinance grew out of complaints made by several residents of the 10th Ward to its alderman, against W. R. Taunton, a bee-keeper. We understand that Mr. Taunton is prepared to test the legality of the ordinance, and is backed by the National Bee-Keepers' Association, and also the New York State Association. Personally, we are in favor of having the matter pushed to the fullest test, as we are very confident that no such ordinance is legal anywhere. Of course, there may be certain instances where the keeping of many colonies of bees is not advisable on account of the locality being closely built up with occupied houses, and yet, even in such a place, if the bees were kept on the roof there would likely be no danger whatever. This is the case in several places in Chicago, and so far as we can learn there has been no complaint from the neighbors. Whenever there is trouble it usually grows out of some spite or jealousy on the part of those living near the bee-keeper, and very likely from troubles arising from other sources than the bees.

We understand that in several other cities in this country there are municipal ordinances prohibiting the keeping of bees within the city limits. We do not know whether their legality has yet been tested, or whether the bee-keeper has simply moved outside. We certainly would not encourage the keeping of bees in thickly settled portions of any city, even though no harm would come from it to any one. But there are many portions of every city that are so sparsely settled that there is no reason at all why bees could not be kept, if so desired. Bees in such places are not only a source of pleasure, but often yield profit to their owners. It would hardly be advisable to make a business of bee-keeping in some cities, but in a large one like Chicago, where there are hundreds of acres of vacant property within the limits of the city, it

appears to work all right. In some portions of Chicago there are almost whole farms that will not be divided into city lots and built upon for many years to come. There is no reason why hundreds of colonies of bees should not be kept in such places, especially when there is such an abundance of bloom that is going to waste for the want of bees to gather the nectar.

In view of the many demands upon the National Bee-Keepers' Association for funds to be used in the defense of cases which are constantly coming up for settlement, it behooves every bee-keeper to send in his dollar and become a member. No one knows when he may have trouble of his own, in the settlement of which he will be glad to call upon the Association. We wish that all readers of the American Bee Journal were members of the National Bee-Keepers' Association. Even if any of them should never need its aid, they have the satisfaction of contributing to what has often proved a "Gibraltar of Defense" in the pursuit of bee-keeping. It should never lack for funds to carry on its righteous wars.

Breeding for Good Stock.—The Luxembourg Bztz, gives some of the principles that are held by Swiss bee-keepers:

Parents transmit their good qualities with more or less certainty to their posterity. The longer a trait of character is continued from generation to generation, the more certainly it is transmitted. The more alike the parents are in their traits without being nearly related, the more surely are those traits transmitted. Every country has its own conditions, which, in the course of time, affect the character of its animals, so that the natives are the best for that country.

As to the last item, it might be said there is no native race of bees in this country, and the fact that the black bee was first imported into this country by no means settles the question of its superiority, for this country.

Slow Cooling of Wax.—The American Bee-Keeper quotes the Progressive Bee-Keeper as saying "the color will not settle." Probably both will admit that the dirt settles, and when the dirt settles the color of the dirt settles with the dirt, and the color of the dirt, as well as the dirt itself, is part and parcel of a cake of wax in which the dirt has not settled.

Unpainted Hives are discussed by G. M. Doolittle in the American Bee-Keeper. He figures as to the matter of economy. He has hives and covers 20 years old that are still good. If he had kept them painted it would have cost him \$1.15 for the 20 years for each

hive, while 48 cents will get that part of the hive new. It is only single-walled hives that he believes should be left unpainted, the advantage being that in unpainted hives the dampness has a chance to dry out. To the objection of Arthur C. Miller that the inside coating of bee-glue prevents evaporation, he replies that "with the freezing of winter and the moisture coming in contact with it, the bright, shiny surface of this varnish becomes dull and full of very fine cracks and holes so that moisture and air pass through it."

Honey as a Remedy.—We desire to call particular attention to the article by Dr. Jas. McLean, on another page of this issue. It will repay a careful re-reading and heeding. Bee-keepers and their families ought to be the healthiest people on earth. Undoubtedly they would be very much healthier than they are if they really knew how best to utilize one of their most common home productions—honey. The reading of a few articles like Dr. McLean's would be a great help to all. It should have a wide reading.

Artificial Ripening of Extracted Honey.—W. S. Hart, in the American Bee-Keeper, says he gets more honey and a more uniformly high-grade article by extracting it when one-third capped, and ripening it artificially. He built a room adjoining his honey-house, covered it with glass, and put in an evaporator of tin, in which the honey runs slowly from side to side in a thin stream four inches wide a distance of about 110 feet, under the full heat of the Florida summer sun. By drawing off from the bottom of the tank he gets only the heaviest, while the thin honey at the top of the tank is constantly evaporating.

Pictures of Apiaries Wanted.—All have doubtless noticed that during the past year or two, since using a better quality of paper, we have been endeavoring to present to our readers half-tone pictures of apiaries in different parts of the country. Of course, we are after the nicest and best ones, and it may be that there are quite a large number that have not yet been shown, that are far superior to any that have appeared on these pages. At any rate, we would like to receive good, clear photographs of modern, up-to-date bee-yards for the use mentioned. Should any pictures be received that for any reason we could not use, we will return them, if requested to do so.

It may be those who have not already had photographs taken of their apiaries will be led to do so in the coming summer, by reason of the above suggestion.

Contributed Articles.

Medicinal and Nourishing Properties of Honey.

BY DR. JAS. McLEAN.

A PERUSAL of Prof. Cook's able review of Thomas W. Cowan's book, *The Honey-Bee*, which appeared in the *Bee Journal* for Dec. 20, 1900, suggested the following points on the medicinal properties of honey, etc.:

The physiological effects of honey are singular, though mild and passive in their character. Honey occupies a broad line between alimentation and therapeutics, being both food and medicine; therefore it belongs to that class of medicinal remedies that cure indirectly—that is, by putting the vital forces in such a condition as to enable them to overcome diseased action. Mineral water, cod-liver oil, malt, etc., all belong to this class of remedies.

Before speaking of the curative properties of honey we will note its physical properties.

In the first place, where does honey come from? Some assert that it is a secretion of the bees, others that it is a natural product in plants. If it is a natural vegetable product the laboratory would have furnished us long ago with genuine honey. It must be remembered that the sugar and glucose that bees resort to in flowers and fruits, is never honey until it has passed through the stomach of the bees; and please do not call this organ a "bladder," as some do, for it is virtually a stomach and performs the functions of that organ. The bee gathers into it a saccharine material. After its reception a gastric element is mixed with it for two purposes—one to give it the character of honey, and the other to make it assimilative for the formation of an oil, that is perfect wax.

It is generally supposed that after a bee returns to its hive with its treasure it hurriedly dumps it into a cell and goes out for another, but this is not the case. When the bee returns, because of fatigue and under the stupefying influence of digestion, it has to abide for a time, both to recuperate and to get rid of its burden of honey and wax. We have reason to believe that even after the honey is deposited in the cells it has yet to receive the finishing touch of perfection, which in all probability is given by the younger bees of the colony. They live on the honey imported, and this rich, concentrated food demands an excess of gastric secretion; when coming to a certain point it creates a regurgitation something akin to vomiting. This the young bee economically puts back into the cells, thus completing the process of honey-making.

Another point as to the character of the bee's stomach. As soon as it is unloaded an insatiable sense of hunger and restlessness ensues, which at once forces the old bee to work abroad and the young one at home. We all know how to respect the buzz of the hungry bee, and admire the sweet disposition of the one that has just finished a sumptuous repast. Ah, how rare are family jars when the pantry is ever full! It is Nature's law, all the same.

We go more especially into these details to point out the medical properties of honey. It has two physical elements that make it particularly a medicine, namely: First, an aromatic irritant imparted to it by the stomach of the bee. Second, its ready transformation into fat without those complicated physiological operations necessary to transfer other saccharine elements into this material. These make it at once both a local and a constitutional remedy. Locally it is an irritant, sedative, emollient, detergent, antiseptic, resolvent, rubefacient, and a parasiticide. Constitutionally it is nutrient, demulcent, laxative, deobstruent, alterative, restorative, tonic, expectorant, febrifuge, and antipruridic, as well as containing poisonous properties manifested under peculiar circumstances.

When we say that honey is both an irritant and a sedative we mean that its first effects may irritate, and be followed with a sedative effect. All liniments work beneficially on this principle; the same with the most of eye-waters, etc. The solution of honey as an eye-water proves particularly beneficial on account of its antiseptic, absorbent, or resolvent properties. It cures inflammation of the eyes in the way a solution of boric acid does, that is, mainly by reason of its antiseptic and sedative properties.

The irritant properties of honey are, in a great measure, destroyed by dilution. Therefore, as a topical irritant

where we wish to favor resolution by counteraction it is used in a pure state, or in conjunction with more active irritants. It is its irritant or rubefacient effect, joined with its emollient nature, that precipitates local inflammation into suppuration, and is, therefore, a suitable remedy for abscesses, boils, whitlows, carbuncles, etc. Therefore, woe to one who applies a honey plaster over an inflamed eye in place of the solution. As a rubefacient and absorbent it makes an excellent local application in glandular swelling, and chronic tumefaction, particularly when joined with iodine, iodoform, or mercury.

On account of the temperature of the body it is difficult to keep pure, undiluted honey on the surface. This can be remedied to a certain extent, by saturating layers of cotton flannel, and applying them, changing frequently.

I speak of it as a parasiticide not only in connection with the theory of the pathogenesis of diseases as advocated by Pasteur, Cohn, Koch, Klebs, and others, who have investigated the bacteria, but even those who created several skin diseases, well known to almost every one. Take honey for the destruction of the bacteria, because of its antiseptic, tonic and laxative effects. Its daily use would disarm every dire and malignant disease of its destructive force. Cholera, yellow fever, smallpox, scarlatina, and diphtheria, may run their course as before, but comparatively in such a mild form as to afford but little, if any, anxiety. I speak of honey only as a preventive of malignancy in these diseases, and not as a curative agent.

The constitutional effects of honey can not be fully understood and appreciated, except it be studied from its medical properties, as represented above. All scientific investigation of remedies are made in like manner. It is the text to a long and complicated sermon. Every physician will read in it such a multiplicity of applications as would astonish the uninitiated.

As a nutrient I will not speak of it as a food, but in connection with its properties which serve to arrest certain diseases, particularly consumption. The important features of the medical properties of honey lie in the nutrient, expectorant, deobstruent, and restorative effects in the management of consumption, and its allied diseases.

Now, let us go back to a fact that exists in the process of making honey. No honey could be had if it were not for its ready metamorphosis into oil, or, in other words, in the making of wax, as stated. The great object in the treatment of consumption is to arrest waste. Therefore we resort to the use of oils, or remedies that will readily make fat in the system. But the great difficulty in the way is to get the system to accept these remedies and effect their assimilation. Under Liebig's authority we give sugar freely to make fat, but the system often refuses it. This alone gives us a great advantage in giving honey to stay the waste caused by disease, that we have in no other remedy.

In being assimilated honey is disposed of in three ways. What is not deposited in the cellular tissue as fat is consumed by the liver, and its volatile principle is eliminated by the lungs. This elimination is a matter of the greatest importance as a remedy in all pulmonary disorders. But the most remarkable feature of honey as a sedative is in administration by atomization and inhalation. The spray arising in extracting has been proven to exert a very beneficial effect upon cough and dyspnea, thus revealing its curative tendency.

The most effective and enjoyable way to benefit from the general use of pure honey is to have in every home a ready supply, diluted with, say one pound to a quart of water, placed in a suitable glass or porcelain vessel—metal must not be used—from which about one tablespoonful put into a cupful of warm or cold water and taken at each meal, would benefit one a thousandfold more than the stupidly conventional decoctions with which we daily clog and seriously disarrange our physical and mental machinery. Let any one who suffers from kidney and bladder trouble try this simple and pleasant substitute for one week, and then faithfully report the wonderful results. Blind, indeed, must mankind be to reject one of Nature's very best disease-preventing remedies, in order to temporarily relieve their perverted appetites!

O, that we would learn seriously to feel and honestly to say, with the Psalmist of old: "How manifold are Thy works Lord, God, Almighty, in wisdom Thou hast made them all!"—including the divinely inspired honey-manufacturing bee.

Let me conclude by suggesting a trial of one tablespoonful of pure honey, dissolved in about half a glass of cold water, and one teaspoonful of tincture of myrrh, for the cure of indigestion. San Francisco Co., Calif.

Foul Brood, Fatal Bee-Stings, Etc.

BY PROF. A. J. COOK.

MR. FLORY, of Stanislaus Co., Calif., sends me a sample of foul brood which is not at all typical. He says black or pickled brood is common, but this seemed more formidable. This has not just the same odor as the usual foul brood, and as it is pulled out of the cell, it does not fly back with quite the spring of the ordinary foul brood. Yet it appears so much like the genuine that I believe it is the same with these differences. It is foul brood but not the typical.

We now have a good foul-brood inspector in this county. He is proceeding in just the right way to eradicate this evil, which is not very uncommon in our apiaries, though I doubt if it is so fatal as in the East. Some urge him to burn all. I think he is wiser in treating the disease. In case only one or two hives show the malady, he burns all. If only diseased cells are found in one or two combs, and a few at that, he burns these combs, watches the colonies closely and hopes for no more trouble. In case many colonies are affected he uses the McEvoy method—shakes onto starters, and in four days onto full sheets of foundation. He is very cautious that none of the honey in the old hive, or that stored in the starters, is eaten by bees. He further does a good work by carefully teaching all interested the nature of the disease, the modes of distribution, the necessary caution in working with the bees, that none of the honey shall be taken by any bees.

It is wisest, of course, to work only when the bees are at work, and some are so careful as to work only at the evening time. It is safest to work under a tent. Wise caution alone will prevent scattering the honey and the disease. Let all remember that they can not be too careful.

FATAL RESULTS FROM BEE-STINGS.

A few days ago, two horses were stung to death by bees in Yolo county, near Sacramento, Calif. The driver was also seriously stung, but not fatally. He was driving a four-horse team, and ran onto a hive of bees. The results were as given above. This suggests that in such cases the horses may be taken to a barn, if possible, as the bees will not generally follow into an enclosure. Covering the horses with blankets wet in cold water will stop the stinging and subdue the fever, and will often prove the readiest means to prevent fatal results.

In case a person is severely stung, washing in strong soda-water and covering with cloths kept wet in cold water will do most to allay fever and afford relief.

FAMILY SCROPHULARIACEÆ.

This is a very interesting family of plants. The figwort—a very valuable honey-plant—is one of the inconspicuous examples of these numerous flowers. Like the mints, or flowers of the Labiate family, these flowers are bilabiate. That is, the flower has two lips. One of these has two and the other three lobes.

We have here three very common species of the genus *Minulus*. They are like the snap-dragons of the East. They are known here as the "monkey flowers." Both the above names are suggested by the peculiar form of the flowers. The curious thing about these flowers, as is true of all such irregular flowers, is the form in its relation to pollination. The flowers are called ringent, as they have an open throat. The stamens are in two pairs, one pair being longer than the other. These are close up to the upper lip of the flower, as is also the style and stigma. The stamens do not shed their pollen at the same time that the stigma of the same flower is ripe for the pollen. Thus the flower can not be pollinated by its own pollen.

Once I saw all the bees going into the hives, curiously striped along the backs with white. They looked like Hereford cattle. I sought the cause and found the stripe was made by white pollen-grains. I sought its source and found it in the yellow-spotted snap-dragons. This was in Michigan. I find our monkey flowers here also have the white pollen, and are quite attractive to sweet-loving insects.

In all of these species of *Minulus* the lower lip of the flower, where the bee alights, and which must sustain the insect as it pushes in to reach the nectar, is strengthened by two prominent ridges, which, from both their form and position, must tend marvelously to give strength to the thin petals, or lower part of the flower-tube. If Nature does abhor close pollination, as some one has said, then surely these interesting plants are well fashioned to prevent it.

Los Angeles Co., Calif.

Prevention of Increase—Other Matters.

BY G. M. DOOLITTLE.

IN a letter from a correspondent I find the following: "What is the best way to keep down increase? The colonies which I now have furnish all the honey my home trade demands, so that I do not want to increase my number of colonies further than I now have. Please answer through the columns of the American Bee Journal."

The surest way is to give plenty of comb-room, and then extract closely till the swarming season is over. Probably not one colony in 50 will offer to cast a swarm treated in this way. In fact, very few colonies will offer to swarm where tiered up for extracted honey, and the extracting not done till the end of the season, providing that empty comb-room is given as fast as needed. But when working for comb honey the case is different, and the bees are almost sure to swarm, no matter how much section-room is given, or whether these sections are filled with foundation or not.

I know of some apiarists who keep their apiaries at the original number of colonies, while working for comb honey, by uniting the colonies about three or four weeks before the honey harvest, making one colony out of two, they preparing for this in advance by keeping each colony shut on only half the combs contained in the hives they use, making the stronger help the weaker till all have the half of their hives just solid with brood, and then let them divide by natural swarming to the original number, keeping down all after-swarming. Or you can let them swarm without uniting before the honey harvest, and, after the honey season is over, unite back to the original number. This accomplishes the same object as the former, only the colonies are not as strong in numbers for storing, and it gives more mouths to feed after the honey harvest is over, with, as a rule, less results in section honey.

Swarming is the bane in comb-honey production, and Dr. C. C. Miller and myself are waiting, and living in hopes, that some bright bee-keeper will yet invent something, or evolve some plan, which will entirely do away with the swarming desire in bees, so that they will work all the "livelong day," and all the days of the season, with the vim manifested by a new swarm, with no such a thought as swarming ever entering their heads. What fun there would be, then, in having a number of out-apiaries, and all piling up the comb honey—yes, and home apiaries, also.

DRONES FROM VIRGIN QUEENS.

Another correspondent writes thus: "Please tell us through the columns of the American Bee Journal whether virgin queens ever lay any but drone-eggs? And are the drones from these queens capable of fertilizing other queens?"

To the first question I think it would be perfectly safe to answer no, although one or two cases have been reported looking a little as if a virgin queen might have produced a few eggs which matured into workers; but I think this can not be other than a mistake.

The second question is one which has not been settled satisfactorily to all minds. Some claim that such drones are just as good as any, arguing from a scientific standpoint that it must necessarily be that, as the drone is the "son of his mother," he could not be otherwise than as perfect from a virgin queen as from the same queen after becoming fertile. On the other hand, some of our most practical bee-keepers claim that such drones are not capable of fertilizing queens, and give instances where plenty of such drones were flying but no queens would get to laying till drones from mated queens began to fly, when they would become fertile and make good mothers.

I have had very little personal experience going to prove the correctness of either, but have always supposed drones from a virgin queen, when reared in drone-comb, were as good as any. Such drones, when reared in worker-comb, may be virile, and even were they not so, I would not expect any queen to prove first-class which had mated with a drone reared in a worker-cell.

Who can tell us more along this line? A practical article by some one having experience in these matters would be read with interest by thousands of apiarists.

"OUTGO MUST ALWAYS BE LESS THAN INCOME."

This is what Prof. Cook tells us is necessary if happiness is to result. (See page 248.) And I agree with him exactly as applied to successful business, or to "successful" health. But when he intimates that the "balance of trade" between this and other countries is "very cheering," because our exports exceed our imports, I can not harmonize his logic; for this, to our nation, is like Macawber's "Annual income,

20 pounds; annual expenditure 20 pounds-six," which can only result in "misery" to the United States. And I can not, for the life of me, see why Prof. Cook and others can see aught but misery to a nation in that which would be misery to an individual.

The papers tell us that during the last four years this country has sent out \$2,150,000,000 more wealth than it has brought in—in other words, it has got rid of that much wealth for which it has received no equivalent. The monopolists (and if I read Prof. Cook aright, he also), calls that trade "in our favor," but just how I have trade in my favor when I give another more than I receive back, is not clear to my muddled brain. Will Prof. Cook explain the matter to us? Don't any one say this has nothing to do with *bee-keeping*, for it has very much to do with it, and with the happiness of the bee-keeper and family.

Public documents, covering the subject, show that there has been over \$4,000,000,000 more gold and silver and merchandise sent out of this country in the last forty years than came back. What did this country get for it? They were not paid in gold, for more gold went out than came back. They were not paid in silver, for more silver went out than came back. And Prof. Cook tells us, "This is all very cheering." Well, it may be to him, but it is very depressing to me; for in it I can see only the "sickness" and eventual ruin to the bee-keepers of the United States. Onondaga Co., N. Y.

Experiences With Swarming, Hive-Making, Etc.

BY J. B. ALEXANDER.

I HAVE been keeping bees for three years. My text book is "A B C of Bee-Culture." I take two bee-papers, the American Bee Journal being one of them. I like them very much, because I think they are published by good men—men that try to do the right thing.

Last spring I had a colony of bees to swarm; I caught and caged the queen, and let the bees return, as I did not want the increase. In 15 or 20 minutes I looked through the brood-chamber to cut out the queen-cells, and the first cell I found the queen had just hatched—I saw her on the frame that contained the vacant queen-cells. I cut all the queen-cells out that had not hatched, being very careful not to leave one. I let the newly hatched queen stay in the hive. I noticed there were eggs in the combs at the time. In six days from the prime swarm they swarmed out again, clustering for half an hour, then returned to the hive. I looked the frames all over again, shaking the bees all off of the combs to see if I had left another queen-cell. I found nothing but the cell that had first hatched, and one unsealed queen-cell with a larva in it. I cut this out and they did not try to swarm any more.

My next experience with the peculiarities of bees was in dequeening a colony of five-banded bees (these being the only five-banded bees in this portion of country). I noticed in the course of half an hour a great quantity of dead bees in front of the hive. I watched them for quite a while to see if robbing was the trouble; there was no robbing at all, for the bees all had the same number of bands, so I was sure they were having war among themselves. I opened the hive, and to my great astonishment it appeared to me that every bee in the hive was in a state of war with one of its mates. I swept the dead bees from the bottom-board, which I am satisfied would have filled a quart measure. I closed the hive quickly, and smoked them with tobacco-smoke at the entrance. In five minutes they were perfectly peaceable.

Now some one will say that it was caused by robbing, but everything went to prove that there was no robbing going on.

I make my hives 16 inches long inside measure, and 12½ inch inside. I cut the frame-rabbits ¼ of an inch deep and ¼ inch wide, and cut a piece of tin 12½x2 inches, and double it so it is 1 inch wide. I then file nine notches in the round edge (caused by doubling) of this piece of tin. Commencing 13 16 of an inch from one end, I file the notches 1½ inches apart. I then nail the tin in the hive so that the edge that is notched will come within ½ inch of the top edge of the hive. I prefer the top-bars and end-bars just 1 inch wide instead of 1½ inches. Instead of letting the top-bars extend over to hang on the rabbits, I drive a 4-penny nail in the center of each end of the top-bars; as my top-bars are only ½ inch deep, driving the nail in the center of the end of the top bar makes just a ¼ inch space over the frames. The notch in the tin should be 1 10 inch

deep, letting the nails rest in the spacing notches, thus giving correct spacing. I let the nail extend ¼ inch to hang the frame, and to hold to while manipulating the frames. I do not suppose this style of hive and frame would suit every one, but if any reader has much propolis to contend with I would be glad if he would try my style of hanging frames.

I send a photograph of my family, and a part of my apiary, taken in February, 1900. Pulaski Co., Ark.

"Long-Tongued Bees—Fad or Fallacy, Which?"

BY DR. C. C. MILLER.

THERE is danger that too much may be expected from length of tongues in bees, and it is well that attention be called to this. Mr. Doolittle, on page 293, is right in saying, "There are times when it is necessary that a halt should be called" by some one, but when he adds, "and as no one has seen fit to do this, I have felt it my duty to do so," he is hardly going by the book. In *Gleanings in Bee-Culture* for April 1st, page 296, Editor Root says:

"It is only proper to sound a note of warning that the general bee-keeping public must not be disappointed if they get some untested queens that do not come up to their expectations. . . . Again, we are not positively sure that the amount of honey a colony will gather is in direct proportion to the length of the tongues of its bees."

And in the following number this *Stray Straw* appeared:

"You are wise, Mr. Editor, to sound a note of warning against losing our heads and depending entirely upon long tongues. A tall man can reach more apples on a tree than a short one; but two men of equal height may not be equally industrious at gathering apples. —[Yes, and from present indications it may be necessary to continue the note of warning. While I believe in long tongues, and expect great results, yet it is evident that a good many are bound to be disappointed. The fact can not be too strongly emphasized, that daughters from the very best of mothers may prove to be very inferior; and I am afraid that 50 percent of them may be only medium, or no better than other queens in the yard.—Ed.]"

So there were at least two men previously engaged in calling a halt.

Mr. Doolittle is vehement against claiming superiority for long tongues without in the same breath constantly saying that there can be no superiority apart from red clover. It would hardly seem necessary constantly to mention that, but over against all the quotations from *Gleanings* which he gives to show that it is held "that long-tongued bees are just the thing he should have if he would succeed, no matter about red clover, or in what portion of the country he resides;" which he seems to think warrant him in accusing *Gleanings* of misleading or false statements. Over against all this stands out clear and emphatic the utterance of Mr. Root, quoted by Mr. Doolittle, that no one claims that long-tongues have any value except for the sake of the red clover crop. If claims for long tongues have been made by men in the South who have no red clover, that conflict with the utterance of Mr. Root, a man who has sat in the editorial chair as long as Mr. Doolittle ought to understand that it is not an easy thing to edit out all discrepancies. But suppose a man who never saw a red clover blossom should find that long tongues and good working qualities go together, why should he not be allowed to say so without having the accusation of falsity brought against the journal publishing his statement?

I do not believe that *Gleanings* has knowingly published anything but what it believed the truth in the matter, and the innuendos of Mr. Doolittle are not in keeping with his usual charitable spirit. Surely *Gleanings* can hardly be accused of misleading in the face of the distinct utterance by its editor that the red clover crop was the only thing to be gained by longer tongues.

A few words as to the real merits of long tongues. I believe, and have said, that the right thing to do is for every bee-keeper in the land to engage in a united effort to continue only the progeny of such colonies as show a good record in harvest, trusting to records rather than to measurements, yet I do not believe the measurements are without value. It seems a pretty clear case that with long enough tongues there ought to be no difficulty about getting the red clover. If I could get all the red clover honey now going to waste within the reach of my bees, it seems to me I should hardly consider it either a fad or a fallacy. The fact that the midge destroys Mr. Doolittle's chances does not make red clover honey any less desirable to me. We

are not all "mided." Thousands upon thousands of beekeepers are located where red clover is all right except the depth of the flower-tubes.

Without knowing anything definitely about it, I am of the opinion that \$100 would be a low estimate of the gain it would be to me annually if I could have all the red clover honey within easy reach of my bees. At any rate, I would be willing to give \$25 or even \$100, for a queen accompanied by a guarantee that I should have all of said red clover honey; and I do not believe that E. R. Root is such a scoundrel that he would stretch the tongues in measuring so as to palm off on me a \$10 queen for a \$25 one.

Although Mr. Doolittle may have no red clover, he might be willing I should have some benefit, and thousands of others.

McHenry Co., Ill.

Small Neglects Affecting Apiarian Profits.

Read at the last Convention of the Ontario Bee-Keepers' Association.

BY W. Z. HUTCHINSON.

"For want of a nail the shoe was lost;
For want of a shoe the horse was lost;
For want of a horse the rider was lost;
Being overtaken by the enemy and slain;
And all for want of a horseshoe nail."

HOW well this old ditty illustrates the losses that occur in the apiary from little neglects. For want of a pound of feed in the spring the colony may be lost; and for want of the colony the harvest is lost, as there are no bees to gather it. For want of care in disposing of the brood and accompanying bees when a queen is bought, foul may be introduced into the apiary, and the end thereof no one knows.

Most emphatically is bee-keeping a business of details. Of course, there are certain broad principles that must be observed before success can even be hoped for. The apiary must be located where there are honey-producing plants, and there must be bees in sufficient quantity to gather the nectar. The bee-keeper must understand his locality, know when to expect the harvest, and have everything in readiness for it. If in a Northern climate, the bees must be protected in the winter, either by some kind of packing or by putting them into the cellar. If comb honey is to be produced, some system must be adopted that will keep the working force together instead of having it divided up into two or three colonies. But after a man has mastered all of the basic principles of bee-keeping—yes, after he has become conversant with the details—he may lose a large share of his profits simply from out-and-out neglect.

The bees are in the cellar. He does not go near them. He does not know what the temperature is. It may be too low; and, if so, it might be possible to add to the protection afforded by the walls. Boards might be set up around the walls, held in place by strips of wood tacked to the sides of the house, and the space filled in with sawdust. This little care alone might, in some instances, secure the safe wintering of bees that would otherwise perish or come through the winter in poor condition. If the bees are in the cellar under the home of the bee-keeper he might employ artificial heat at those times when it is needed. A large oil-stove having a hood over it, connected by means of a pipe with the stovepipe in the room above, will answer every purpose. A cellar may become infested with rats or mice that will gnaw combs, and do much damage if not gotten rid of. Equal parts of flour, sugar and arsenic placed in dishes in the cellar, will make quick work with the rodents. Mice will play sad havoc with colonies left out of doors if the entrances are neglected. The bee-keeper should know how his bees are wintering. He should not neglect them. A perfect wintering of the apiary lays the foundation for a successful season.

After the bees are placed upon the summer-stands don't neglect them. As soon as the conditions are favorable, look them over. Here and there will be a queenless colony. Here and there will be a weak one. United, such colonies may prove as good as there are in the apiary. Neglected, they will be of little value the queenless ones will certainly perish, perhaps become a prey to robbers, thus stirring up bad blood in the apiary at the time of the year when all should be peace and happiness. Some colonies will be found with a great abundance of stores, others on the verge of starvation. Neglect here means the loss of all colonies that are short of stores.

As the harvest comes on, don't neglect to have the hives, sections, frames, etc., all in readiness. Some of

you may be ready to shout, "Chestnuts!" Well, if only those shout who have never been caught, I think none of us will need to cover up our ears. Nothing will more quickly change the mood, and disposition, and intention of a colony, cause it to turn its energies into a different channel, than the neglect to furnish it surplus room when it is needed. The disposition to store honey is laid aside for that of swarming. A colony with the swarming fever will do little work until that fever is abated. If a colony first turns its energies in the direction of storing up surplus, it will often continue on in this way the entire season with no thoughts of swarming. And, speaking of swarming, reminds me that the neglect to clip off just one little eighth of an inch from her majesty's wing sometimes results in the bee-keeper striking a dejected attitude, as he gazes sorrowfully over the tree tops where he sees disappearing, as little specks in the sky, the last, few straggling members of the rear guard of a prime swarm that would have stored 50, perhaps 75, pounds of honey for its owner had he not neglected to clip off that little one-eighth of an inch.

When it comes to the extracting of honey there is one point that I wish to mention, although it may be more a mistake than a case of neglect; it is that of extracting the honey before it is ripe. Of course, it is possible to evaporate artificially thin honey, but with this evaporation goes a portion of the fine aroma. Not only this, but the evaporation of honey does not ripen it. The bees in their handling of the nectar invert or change the cane-sugar to grape-sugar. They change the raw nectar into ripened honey. If we take it away from them before this change is completed, it lacks that much of perfect ripeness. It lacks the "tang" that tickles our palates. Thin, unripe, watery honey ferments, and sours, and bursts tin cans and barrels, and disgusts and disappoints every one who has anything to do with it. Nothing has done more to destroy the market for honey than the placing upon it of unripe honey.

Little neglects in preparing the honey for market are very expensive. The neglect to scrape the propolis from the sections, the neglect to use non-drip cases, the neglect to put the cases into a larger case or crate when small shipments are made, may mean the loss of two or three cents a pound. Sections daubed with propolis, honey dripping from one case and daubing the one below it, coal dust and cinders rubbed upon the daubed cases, greatly lower the price and retard sales. Before the days of no-drip cases and outside crates I went so far as to wrap a paper around each case before shipment, that the cases might be clean when they reached their destination.

Men who make exhibits at fairs often lose premiums that they might have captured had they not neglected to label their packages tastefully. It is a little thing, but it adds the finishing touch.

Then there are little things, like, "Where do you keep your smoker and fuel?" The neglect to provide a proper place for them may mean a costly fire. I once kept my smoker and fuel in an old wash-boiler. Once upon a time when I removed the cover, the flames burst out. Suppose the boiler had been a wooden box kept in a building, and the fire had not been discovered while still confined to the box? I now keep my smoker and fuel in a large box, with a hinged cover, out in the yard.

The matter of saving wax ought not to be neglected. It is a good deal like saving paper rags—just about as easy to save the odds and ends as to throw them away. A solar wax-extractor is a nice thing for this purpose. Keep it standing in the yard, and when there is a bit of waste comb toss it into the extractor. One year when I did a large job of transferring I threw all of the odds and ends into a barrel, and pounded them down hard with the end of a large stick. Then the matter of rendering was neglected until that barrel two-thirds full of pounded-down comb was one mass of webs and wriggling worms.

But why multiply examples? We all know that the profits of an apiary can be entirely wasted or destroyed by little neglects. What is the cause of this neglect? In some cases it is simply a combination of indolence, procrastination, and a sort of belief that things will come out all right of themselves. Then there is the neglect that comes from having too many irons in the fire. If you have so much business that you can only half attend to it, that something must be neglected, two courses are open: hire some one to help you, or else dispose of part of your business. There is more pleasure and more profit in a small business well managed than in a large business that must be neglected. Some men are so constituted that they can not employ help to advantage. They have done all of their

work so long that they feel no one else can do it properly. It would put them all in fidgets to see some one else cleaning their sections, or uncapping combs for the extractor. Other men have learned that it is much more profitable for them to oversee and plan the work, leaving the carrying out of the details to competent help. You know yourself, or ought to, so choose the course to which you are adapted, but don't keep on conducting your business in such a manner that you are compelled to neglect it. Be thorough, up-to-date, progressive, and energetic, but don't lose half your profits as the result of little neglects.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Queen Laying Several Eggs in a Cell.

What is the cause of a queen laying from one to four eggs in a cell? It is a weak colony, with a hive full of honey, and some chilled brood. It is not a laying worker that is doing the laying, but a fine, large queen.

UTAH.

ANSWER.—The colony though small is lively and ambitious, and the queen is probably fed as much as she would be in a much larger colony. The eggs must be laid somewhere, and as the space that is warm enough for egg-laying is too limited there is nothing for her to do but to use the same cells over again. As the colony becomes stronger you will find that she lays only one egg in a cell.

The Nail-Spaced Frame Preferred.

I have had more of the Hoffman frames than I want, and as I have sold all my bees and fixtures, and wish to start this summer, I wish to know first if the Danzenbaker is just as bad to manage for the reason of propolis, and are the general features as good as the nail-spaced Langstroth standard?

ILLINOIS.

ANSWER.—The Danzenbaker frames are closed-end frames in full, and the Hoffmans partly closed, so there is more surface in contact to invite propolis in the former than in the later. After giving a pretty thorough trial to both, and also to some other kinds, I find nothing so satisfactory as the Miller frame already described in these columns. I commenced using them on a somewhat small scale, feeling a little afraid that continued use would develop some objection not suspected in advance, but the more I use them the better I like them, and have perhaps 2,000 of them now in use.

Keeping Down Increase.

1. I have five colonies and do not wish to increase. The swarming-fever struck them about a week ago and has not stopped yet. A neighbor told me how he does but I do not like the plan, viz: Take a soda-cracker box which is about 8x10 inches, and about 8 inches deep, and put the cluster into it, and place a bottom-board over it. Take it to a new stand, invert it, and as an entrance has been previously made we have a new but small hive which my neighbor says will be filled solid.

Yesterday one of these swarms came out of the box three times, clustering on the same spot each time. The third time I gave them a new box with two pieces of foundation stuck to the top 4 inches wide, and they seem to stay all right. The neighbor says early in the spring he gives these cracker-box bees back to the original colony, and has a fine colony to begin the harvest, and then repeats with the same boxes next year. This is my first experience with bees, so I don't like to fall too heavily on my instructor, but it does seem to me that the number of bees which I have put into those small boxes will be terribly crowded.

What was the reason of those bees coming out three times? As I am a half-invalid, through eight years of throat affection, it nearly exhausted me, going to and fro.

2. Now, to-day, another swarm came out of the hive that swarmed day before yesterday, at which time we requeened the colony, killing the old queen, of course. The cell containing the new queen just hatched yesterday. How can you account for to-day's swarming with such a new queen? or do you think the new queen never materialized? Would they swarm under those conditions? We cut out all the rest of the queen-cells in that hive.

CALIFORNIA.

ANSWERS.—1. I'm a little inclined to think I'd pay off that instructor and hire a new one. To put a strong swarm into a box containing no more than 640 cubic inches—less than 10 quarts—in these days of expansion is pretty severe contraction. The combs built are not in movable frames, hence not the most desirable. The probability is that the bees were too crowded and warm, and swarmed out on that account. Shading well and raising up the box an inch from the bottom-board would help. If your object is to keep down increase, perhaps this plan might suit you better: When the colony swarms, kill the old queen and return the swarm. If your queen is clipped all you have to do will be to pick her up from the ground and kill her, and the swarm will return of its own accord. A week later cut out all queen-cells but one, and the work is done. There will be no more swarming for that colony till another year.

2. If I understand you, when the colony swarmed you killed the old queen and returned the swarm, killing all the queen-cells and giving them another cell, then two days later the colony swarmed again. It is not easy to say just why they swarmed the last time, but there are several possibilities in the case. One is that a queen may have entered from another hive. Another is that the cell you gave may have been well bees, so the queen having been held in some time by the advent of that two days after you gave the cell she was old enough to make her wedding-flight, and the bees swarmed out with her when she made this flight, which is not a very unusual occurrence.

A Question on Bee-Management.

White honey is produced in this locality early in the spring, and the nights here on the coast are cool so the bees fall to breed up to good working force in time to get the first flow. How will it do to form a nucleus say in June, and in the fall place it on the old colony with an excluder between; then when both are well filled with brood take out the excluder and kill one of the queens in the spring?

FLORIDA.

ANSWER.—I don't know. I doubt if it would work to your satisfaction. The object would be to throw, in the spring, the force of the two queens together. I suspect you might do that better by having the two colonies side by side in the same hive with a thin division-board between them but no communication between the two sides. Then in the spring they could be thrown together. But it would be worth while to try very hard to have colonies so strong in the fall that there would be little need for uniting in the spring. Then the weakest could be united with the medium ones.

Managing Bees in a "Beer-Keg Hive."

I have a very strong colony in a "beer-keg" nearly filled with honey. I propose to add one or two 8-frame hives underneath until the white clover flow begins, then change them to the top of the keg with a queen-excluder between, with the queen below. Will the bees carry the honey upstairs and make room for her to lay? I will let the brood alone until hatched, then put on sections. My idea is to get the honey now in the beer-keg in sections, and let the bees winter in the keg.

INDIANA.

ANSWER.—I'm afraid that thing is so mixed up that the bees will hardly know what is expected of them, especially if there's any of the beer left in the keg to muddle their little brains! Evidently, your idea is that the keg will be so filled with honey by the time of clover that the bees will have worked down so as to fill one if not two stories of combs in frame hives.

That may be so, and it may be that they won't come up to your expectations and will have very little done in the hive under the keg. Suppose, however, it works to your

satisfaction, and your two hives are fairly filled, it will be mostly brood in them. When you put them above the excluder, the queen you will put below in the keg that is now solid with honey (for you may count that it will be filled with honey if the bees have been driven down to occupy the two hives). At this time the bees will turn all their energies toward storing, and the likelihood is that while the bees will do some emptying to give the queen a chance, the chance will not be a very large one, especially as the queen up to this time has had unlimited room to spread herself and by this time has become somewhat exhausted with laying. The brood will be all the time hatching out above, and by the time your two hives are solid with honey there will not be such a great deal of time left for the bees to work in sections, for they'll not do much in sections so long as room is left in the hive-bodies. I don't quite see what you expect to gain by getting your keg filled with honey only to be emptied again. If you want the bees to winter in the keg, why not leave them their brood-nest there all the time, putting sections on the keg? One good plan would be to leave them in the keg till they swarm, then hive the swarm in a hive and throw the hive-force all into the swarm, leaving the keg to strengthen up for the winter.

Transferring Bees on Crisscross Combs.

I bought two colonies of bees and they are in small hives, one is a seven-frame and the other is an eight. The frames had no foundation, and the comb is built in every direction. Is it advisable to transfer them to another hive? If so, when is the best time? and will that prevent them from swarming? ONTARIO.

ANSWER.—If you don't expect to handle the frames at any time, then it is not worth while to transfer, and it will be better to leave the bees as they are. If, however, you want to handle the frames at any time, then by all means they should be transferred. You can turn the hive upside down if the bottom can be taken off; cut down with a long knife or saw so as to loosen entirely the combs from the side of the hive, then when you lift the hive-body off the frames it will be easy to get at the combs.

In fruit-bloom is a good time to transfer, and it need not prevent swarming. Nowadays the tendency is growing toward waiting till the bees swarm, and transferring 21 days after swarming, when there will be no brood in the hive except a little sealed drone-brood.

Curing Pickled Brood.

What can I do to cure pickled brood?

WEST VIRGINIA.

ANSWER.—In an able article in this journal five years ago, Dr. Wm. R. Howard wrote: I have recommended, with successful results, placing the bees on full sheets of foundation, confining them for three days (giving them plenty of water) in order to consume all of the infected material, that none of it might be deposited in the new combs to be covered with new pollen or honey.

Convention Proceedings.

Report of the Chicago Bee-Keepers' Convention.

The Chicago Bee-Keepers' Association held a most successful meeting at the Briggs' House, Chicago, April 4, 1901. There were about 35 in attendance, and several new members were secured.

The secretary had had some correspondence with Mr. C. P. Dadant, about being present, and had given up hoping he would come. But about 10 a.m. on April 4th a telegram was received by Pres. George W. York, saying that Mr. Dadant would arrive at the Union depot at 2:30 p.m. Of course this was an agreeable surprise, but if we had known it a week earlier we might have filled the clubroom of the Briggs House at our meeting.

I would like to say right here that those 250 bee-keepers

within reach of Chicago, are standing very much in their own light in not attending our semi-annual meetings. We have really good times and exchange many valuable ideas.

Of course Mr. Dadant's presence made a good convention, aside from any other attractions. He told us about Paris and the great Exposition; about the French people; about the little old man who had carried him in his arms when he was a very small child; and of course he was ready to answer any and all questions asked of him by the A B C class of bee-keepers as well as the X Y Z class—and the questions were numerous.

Prof. E. N. Eaton, State Analyst of the Pure Food Commission, was present, and addressed the meeting, and also forced his annual dues on an unwilling treasurer.

At 6 p.m. those present adjourned in a body to the dining-room, and discussed many and savory viands, and had much sociability therewith.

It was voted that the afternoon-and-evening-session idea be a permanent fixture. We hope all those 250 bee-keepers will come to the next meeting in November. Dr. Miller and Mr. C. P. Dadant may both be there.

I am sure all present were sorry when the meeting adjourned at 9:30 p.m. HERMAN F. MOORE, Sec.

Report of the Texas Bee-Keepers' Convention.

The Texas State Bee-Keepers' Association held its 23d annual session at Greenville, April 3 and 4, 1900. President W. R. Graham being sick, was not able to preside, and vice-president A. M. Tuttle being absent the meeting was called to order by the secretary, J. N. Hunter, who acted as chairman. He made a few preliminary remarks, reviewing the history of the Association from its organization to the present time. Prayer was offered by the Rev. W. R. Lowery.

Messrs. Hagood, Osborn and Scott were appointed a committee on program for discussion.

About 40 bee-keepers were present during the two days' session, representing some 2000 colonies of bees, the average yield of which last season was about 36 pounds to the colony.

Secretary Hunter explained his method of transferring bees. He prefers the hybrid bees and uses full sheets of comb foundation.

J. M. Hagood thinks the Holy-Land bees are the best for Texas, and that they are more immune from disease.

W. A. Evans has 185 colonies of Italian bees, and secured 50 pounds of comb honey per colony last year.

J. R. Scott explained his method of transferring and feeding bees. He gives the black bees due credit for gathering honey from cotton.

Peter Lambert and some others are satisfied that bees gather honey from corn-tassels.

Mr. Tuttle has discovered that ants rob cotton-bloom of its honey on the sandy land. He thinks that is the reason why bees gather more honey from black-land cotton-bloom.

Messrs. Graham, Hagood and Lowery were elected to represent the Association at the bee-keepers' meeting to be held at College Station, Tex., next July.

W. R. Graham was re-elected president; J. M. Hagood and W. R. Lowery, vice-presidents; and J. N. Hunter, of Renner, secretary.

After its usual vote of thanks for hospitality and entertainment the convention adjourned to meet in Greenville the first Wednesday in April, 1902. J. N. HUNTER, Sec.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

The Chicago Convention Picture is a fine one. It is nearly 8x10 inches in size, mounted on heavy cardboard 10x12 inches. It is, we believe, the largest group of bee-keepers ever taken in one picture. It is sent, postpaid, for 75 cents; or we can send the American Bee Journal one year and the picture both for \$1.00. It would be a nice picture to frame. We have not counted them, but think there are nearly 200 bee-keepers shown.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

EARLY QUEENS FROM THE SOUTH.

As per Dr. Miller, on page 219, queens may arrive from the South when it's not altogether safe to introduce them. General requeening with young queens is often urged; and I think that this particular danger is very seldom pointed out. Usually a word to the wise is sufficient; but if it is a printed word he may not see it—so I think a little more "racket" on the point would be well. Doubtless the Southern breeders will be willing to assist in the racket—to moderate the push for extra-early queens.

QUEER KIND OF CHAFF HIVE.

Mr. Ochsner, of the Wisconsin, seems to have a queer kind of chaff hive. Pumps down heat so that melting occurs, and frames and colony have to be put into single-walled hives to stand the sun. That's not the kind of chaff hive which prevails elsewhere on the footstool. Page 229.

WEAK COLONIES IN THE SPRING.

Why does a weak colony in spring survive when left alone, but dwindle out and perish when united with several others like itself? I had made an off-hand guess that although not fighting when united they felt more like fighting than they did like going to work—disrupted at the mixed company. Am quite willing to give up my guess in favor of Mr. Doollittle's more thoughtful solution—too much activity, too much brood started, and nearly all the bees dying off, in regular course of nature, before any young bees emerge. Page 231.

SWARMS CLUSTERING WITH CLIPPED QUEENS.

Prof. Cook gives us a good, hearty stake to tie to on page 232. Has seen hundreds of swarms issue whose clipped queens could not go with them; and only a few in the lot failed to cluster (either wholly or in part) before going back.

HYMENOPTERA—"MARRIED WINGS."

I'm a little disrupted at Prof. Cook's Greek on page 233, where he translates Hymenoptera (the order to which our bees belong) "membranous wings." Don't wish to deny that the word will bear that translation, as meanings of words go; but what in Hymen is the matter now with the straight-out translation "married wings?" This is an allusion to the fact that each wing is bound to its neighbor on the same side by a series of little hooks. Has marriage become a failure even among the wings of bees?

DISCIPLE OF IZAAK WALTON.

And, so, according to page 238, its fishing you're going to set me at next. On the familiar principle, that a man can go on the most freely on a subject when he draws it fresh out of his own head (unperished by facts and natural laws and experiences and things), I ought to be able to write a two-volume work on fishing. Tell Mr. Blunk it's 57 years this spring since I cast my first hook in the waters for fish. But I didn't catch any. Neither did I on any subsequent occasion. Never in my life caught even a minnow the size of your little finger. Send in your sub, for the volumes, if you want 'em.

WHY BEES BUILD A CERTAIN KIND OF COMB.

It is something of a mystery—and a mystery that we should very much like to solve—just *why* bees build worker-comb when they build it, and drone-comb when they build that. One rather feels that Mr. C. P. Dadant is walking on the water instead of touching bottom in that part of the subject, page 246. The facts are as he states them; but the reasons—well, we must show some respect to the reasons, too, till some one can offer better ones. In fact, if we assume that (for some unknown reason) bees *prefer* to build drone size, except when the queen (by some unknown means) causes them to build worker size, that will pretty nearly cover the ground, perchance. If the queen caused them to do it we would not need to assume that she intelligently caused it, nor yet that they fully understood the effect of their own work. But even then we might have trouble to answer when asked: Why then do they build any worker-comb in an upper tier of sections?

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

Polish Up the Dark Side.

Is life a fret and tangle, and everything gone wrong?
Are friends a bit disloyal, and enemies too strong?
Is there no bright side showing? Then—as a sage has said—
"Polish up the dark side, and look at that instead!"

The darkest plank of oak will show sometimes the finest grain.
The roughest rock will sometimes yield a gleaming golden vein;
Don't rail at fate, declaring that no brightness shows ahead,
But "polish up the dark side, and look at that instead!"

—PRISCILLA LEONARD, in The Churchman.

A LESSON FROM THE WAX-PRESS.

I am sure we have all been interested in the new method of extracting wax where the press is used, and where great saving of time, and a much larger quantity of excellent wax are secured. What a valuable lesson Christ taught the world at the time of the feeding of the multitude. It was a great occasion, and any one less than Divinity would hardly have thought of the fragments. Yet the blessed teacher of Nazareth asked that the fragments might be gathered up and nothing be lost. Many a man to-day is in comfortable circumstances because the fragments have been gathered up. Many home circles all over our land rejoice to day in numerous home comforts, not to say luxuries, because in early childhood the builders of these homes were taught the little economies which are not only helpful but really give pleasure in their practice. It certainly can not be beneath any person's dignity to form, or to teach, habits of economy when the Divine Master put the stamp of his approval upon this very habit. I have always been thankful that my dear father and mother taught me to make a thin paring as I peeled the apple, and to reduce the core to the minimum before it was thrown aside. So I am always glad when I see anything like these wax-extractor improvements, and rejoice that our friend, Mr. Hatch, and others, has given us the press that we may glean more, and more easily.

It is often the best of economy to save strength and time. How short-sighted people were to declaim against inventions. Whatever saves labor benefits our people, and gives to us all more of the comforts and blessings of life. It is not labor-saving machinery that brings inequality of conditions, divides classes, and creates social unrest. It is rather the abuse of these privileges, and the taking advantage of circumstance. Were we all to follow the Great Master in all his teachings, labor-saving inventions would bring only blessings in their coming.

I believe the world never had so many blessings as to-day. I believe there was never a time when the poor boy or girl who has energy and economy could reach forward so confidently towards position, and even wealth. I was happy the other day in telling my students of a man who once drove horses on a canal path, who had no father or mother to train him in ways of thrift or economy, and yet to-day occupies honored positions in two of our great universities. His name is known in every country where science is studied. Garfield had a grandmother to help him to thrift and position. Our friend found both with no help except his own inherent determination and power. I said to our students, "Haven't we a grand country, and don't we live in a grand time?" Whenever I read of anything like the wax-press, I feel like praising God for another step forward.

But there is another thing in connection with this wax-press which is to me more beautiful than the economy, and it is this that brought it into "The Home Circle" to-day. I refer to the fact that it removes this work from the house, and thus saves the wife and mother from much of labor and annoyance. I believe there is nothing that will test the good-nature and amiability of the housewife more than the presence of wax about the kitchen and the kitchen utensils, which are a part of the special equipment which she has to use. It was good to hear the men say in speaking of the wax-extractor, "It takes all this dirt and annoyance from the house." I believe this is the best part of the new invention,

and it is better still that the most of our bee-keepers will prize it most because of this very fact. Any one who knows Mr. Hatch and his kindly thoughtfulness, can readily understand his satisfaction as he removes this wax dirt from the domain of the household. Some may wonder that I speak of wax as "dirt." A weed is a plant out of place. Dirt is matter out of place. Purslane (pusley) on the common or by the roadside is no weed. In the garden or field it is a pestiferous one. Wax taken by the new method outside the house is neither dirt nor dirty. Inside the kitchen it is usually both.

THOUGHTFULNESS FOR OTHERS.

The above suggests what I believe will prove the best ornament in every home circle. I mean thoughtfulness to help and to give pleasure to all its members. In many a home the thoughtful habit becomes almost instinctive. If any member of the household has the habit of rising earlier than the others, he will also form the habit of great quiet before the others rise from their beds. Thus at this earlier hour he will find himself tiptoeing about the house, which he would not think of doing later in the day. The door will be carefully shut and will not slam, and the fire-lighting will be done so quietly that one wonders that so little noise is possible. This caution may become so instinctive that it will even last through the day, as I have known the father frequently to find himself tiptoeing even in the daytime as he approached the sleeping-rooms.

It has been my privilege in my past life frequently to pass, often quite late in the evening, by the house of an old gentleman whose habit it was to retire early, with a person whose thoughtfulness for others' comfort was always an inspiration to me. This one, as we approached the house of the old gentleman, would always lower the voice or cut short the laugh which might awaken the sleeping one. This reverent thoughtfulness did more to beget thoughtfulness in others than would a dozen requests to act in like manner.

We often hear people lamenting that there is so little reverence at the present time among us. I believe this implies an error. I believe there is more genuine reverence among us to-day than there has ever been before. Yet, I am not wholly displeased at the complaint. Want of reverence is so hateful a thing that even fear that it is a growing evil may well cause unrest and regret. We must remember in this day of telephone and rapid transit, we have pictured to us the whole world, each day, and our fuller knowledge often misleads us in regard to the condition of society.

I repeat, I believe the world never had so much of reverence as it has to-day. It is certainly true that nothing so increases the reverent spirit among us as thoughtfulness. There is no place where thoughtfulness pays such large interest as in the home. I remember once a girl asked me for a sure test in selecting the right person for a life companion. I believe I made the correct reply: "The person who is ever thoughtful of father, mother, yea of all the members of the home circle—always intent to add to the pleasures of others, and equally careful never to wound or make uncomfortable—has a first requisite of the perfect husband."

Unselfishness must always be at the root of thoughtfulness. Unselfishness is a Godlike attribute. If we can only teach our children from the very cradle always to be thoughtful of the happiness of others, and always to be on the lookout for opportunities to make the home more a place of comfort and good feeling, we surely have done our part toward the building of an unselfish and a reverent character.

In the years when I lived at the Michigan Agricultural College, it was my habit to drive of a Sunday morning with my wife and family to the church in Lansing, three and a half miles distant. In going, we almost always passed one of the business men of the city going with his family to the same church. A little boy of this family invariably walked beside his sister. In the early years, up to the teens, they were always hand in hand, and the evident attention of the brother, and watchfulness for the comfort of his little companion were often the subject of remark in our family as we passed the little group. That little couple, all unconsciously, were helping us to become better people. As the young people grew into their teens, the same attention on the part of the brother was always in evidence. Walking on the windward side, picking up a fallen handkerchief, stopping back to let the others pass first into the church, were all signs of a lovely character which from the first challenged our admiration. Mrs. Cook often remarked, "There is the making of a model husband." Time proved that her judgment was not ill-founded. There are a few things which we in the home circles should never forget: love of truth, self-control, and this habit of thoughtfulness; it is a trinity of blessed qualities, and means so much not only to the life of the individual

but to the comfort and blessedness of the home, that we should commence at the very cradle to speak their importance to the loved ones whose characters we are to fashion.

NEATNESS AND ORDER—A FOURTH VIRTUE.

It has been my happy fortune to visit very many of the bee-keeping homes of our country. It is always a rare treat to visit those who are interested in the same things that occupy our thought and attention. But as on the street or in the audience-room, one of the best pleasures comes from the study of others, their habit and manner, so in these visits it is not the least pleasure that comes to us to study the special habits of our hosts.

I remember my first visit to Mr. T. F. Bingham's apiary. I had often met Mr. Bingham in conventions, and was always pleased at his perfect attire and every courtesy, and so was prepared to find his shop and apiary the perfection of order and neatness.

I have one other example that is quite as striking, and no one will wonder that it is suggested. It was that of Mr. Hetherington, who has been so long associated with Mr. Bingham in the matter of the honey-knife. Many of my readers will remember how pleasant it was to look upon Mr. Hetherington at our conventions. One had to see him but a moment to know that system and neatness were ever in attendance at the Hetherington apiary. And so it was. I might mention hundreds of similar cases. Mr. Hilton and Mr. Taylor were other examples. These men never came to a convention without a necktie, or with spots on their clothing. These gentlemen had apiaries that were justly their pride. It always gives me unalloyed pleasure to make such visits. These men have not to look for things, for everything is in place, and they could put their hand on every utensil even in the dark. Such system implies neatness, for nothing is out of place, and so from our definition above, there can be no dirt.

I have often wished that it might have been my good fortune to have visited the apiaries of Captain Hetherington, of New York State. I have no doubt he has the same habit of order and neatness that I admired at his brother's. We have all wondered that one man could manage so large a business as is carried on by Captain Hetherington, and win success all along the line. Does not the word system give quick explanation?

We have given above a trinity of qualities so excellent that we should commence at the cradle to develop them in the lives of our children. Would it not be well to make it a quartet, and add the virtue of neatness and order? This can be done by teaching the child always to hang his clothes neatly upon a chair as he retires; to keep his playthings in perfect order; and his room, if we can afford him one, always neat and orderly. Put a premium upon such habits, and if we ever knit our brow in disapproval, let it be upon occasions of finding a disordered room or an untidy drawer or closet. It is well to go often and inspect the drawers, and as we find them all in perfect order, put in them some coveted toy with the words neatly written, "Couldn't help it." Such a neat drawer merits a drawer full of toys.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

The Premiums offered this week are well worth working for. Look at them.

Tennessee Queens!

Fine lot of Choice Tested Queens reared last season, daughters of select imported and select golden queens, reared 3/4 miles apart, and mated to select drones, \$1.50 each; untested warranted Queens, from same breeders, either strain, 75c each. No bees owned nearer than 2 1/2 miles. None impure within 3, and but few within 5 miles. 2 years' experience. Discount on large orders. Contracts with dealers a specialty. **JOHN M. DAVIS,** Spring Hill, Tenn.

SOUTH DAKOTA FARMS

Is the title of an illustrated booklet just issued by the Chicago, Milwaukee & St. Paul Railway, descriptive of the country between Aberdeen and the Missouri River, a section heretofore unprovided with railway facilities, but which is now reached by a new line of the Chicago, Milwaukee & St. Paul R'y. Every one contemplating a change of location will be interested in the information contained in it, and a copy may be had by sending a 2-cent stamp to F. A. Miller, General Passenger Agent, Chicago, Ill.

19A3t

A Young Bee-Keeper's Report.

My grandfather was a bee-keeper, and he gave a colony of bees to the oldest grandchild in each of his children's families, and I, being the oldest in our family, got one of them. We now have 12 colonies working nicely on fruit-blouses.

We make our living mostly by selling section honey and poultry, and would like to have 50 colonies of bees for our own use. My father, I help manage the bees and take off the honey; my father is not able to help any, so we three children all help a little. I am going to school now, but it will be out in four weeks, and then I will help with the bees. I am not afraid of them as a great many people are.

I am a girl of 13 summers, and not a very big one at that. **GERTRUDE HENRY,** Page Co., Iowa, May 3.

Bees in Fair Condition.

At this time our bees are in fair condition, and we hope for a good crop of honey. All our colonies wintered well.

MRS. EMMA WOODMANSEE,

Arapahoe Co., Colo., May 9.

From a Young Bee-Keeper.

I am 18 years of age, and have been trying to keep bees for the last four years. I got up to 75 colonies, and as we had three dry years I lost 60 of them, so you can see we have hard times as well as anybody else.

EARL TUCKER,

Los Angeles Co., Calif., May 1.

An Industrious Lady Bee-Keeper.

We think we will have a good honey crop this year. Our bees are storing in the supers now, and are swarming right along. We have 48 colonies. You ought to have been here last week and the week before. I, myself, put up 75 hives, driving every nail, and then painted them, and caught all swarms that came out. My husband is a railroad conductor, and can't be here to help me, and I do not have anything else on the place. I was out putting up hives one evening when a lady came in. She said, "Do you have to work that way? You have on a gold watch." I said, "I have silk dresses in the wardrobe, but I like to work. My husband tries to keep me from it, but he can't."

I think if more women would work there would be so many better men. Of all things, a lazy woman is the worst. The bees teach us such good lessons. For 20 years my health had been so bad every spring that if I didn't use a tonic I was bedridden; but the little bee is the best tonic. For five years we have kept them, and I am out almost all day with them. I do not need a drop of medicine now. I tell many women if they would get off the streets and stay at home, get a few colonies of bees, watch them, and read bee-books instead of novels, they would be better wives and mothers. They say, "Oh, the bees will sting." Well, if they do it will not last long. I would rather be stung trying to make something than to be stung for the want of something. **Mrs. C. R. West,** Ellis Co., Tex., May 6.

Prospect Good—Bees Stinging Chickens.

We are expecting a good honey crop this year. Bees wintered well, seem strong, and are building up fast at present. Fruit is a little past its best now. Vine maple will be the next to bloom after apple; it makes a very nice honey, and has a flavor like maple syrup.

I have about 30 colonies, mostly hybrids, though some of them are blacks. Last year

PAN-AMERICAN OPENING.

The Nickel Plate Road will sell excursion tickets from Chicago to Buffalo at \$13.00 for the round-trip on each Tuesday in May (the 7th, 14th, 21st and 28th.) with limit of 5 days, namely: returning good on any train to and including midnight train from Buffalo on Saturday following Tuesday tickets are sold. They will be good going on all trains on date sold.

Daily train from Chicago at 10:30 a. m., arrives Buffalo 2:05 following morning; daily train from Chicago at 2:30 p. m., arrives at Buffalo 7:35 next morning; daily train from Chicago at 10:30 p. m., arrives Buffalo 4:45 next afternoon.

All trains carry through vestibuled sleeping-cars. Individual Club Meals, ranging in price from 35 cents to \$1.00, and no meal in excess of the latter figure, are served in dining-cars.

For sleeping-car reservations and all other information, call at Chicago City Ticket Office, 111 Adams St., or write John Y. Calahan, General Agent, 111 Adams St., Chicago, phone Central 2087. Chicago Depot: Van Buren St. and Pacific Ave., on the Elevated Loop. No. 7—20A2t

I took off some very nice well-capped sections on May 13th, and expect to do as well this year.

I have had some experience with bees stinging chickens, which I think will be of benefit to the readers of the Bee Journal. Two years ago I was transferring a colony of bees to another hive. There were some chickens (barred Plymouth Rocks, and, of course, black) about two weeks old feeding in a pen near by, and also some white Pekin ducklings about one week old. The bees went for those chickens and stung them to death, but the ducklings were not stung at all. I think the reason why the ducklings escaped was because they were white, or light-colored; and to prove still further that bees hate black chickens, this year I had a hen with 14 chickens about two weeks old—13 were black and the other one white. The bees went for that brood of chicks and stung all but the white one. Five of the black ones lived, even though they were stung, but they were dumpy for a couple of days. But "Mr. White" was as happy as it is possible for a chick to be. The bees had no provocation to anger whatever that I could see. The hen was on the ground with the chicks about 8 or 10 feet away from the front of the hive, and the hive was 2 1/2 feet from the ground.

I have been a reader of the American Bee Journal for two years, and would not be without it.
Geo. G. CRAINE.
Whateam Co., Wash., May 6.

Bees Expelling Water from Nectar.

I notice there has been quite a controversy in the American Bee Journal, among some of the correspondents as to whether or not bees expel water from the way to the hives. A bee-hunter, and a very successful one, too, says that after a bee has secured its load and starts in a direct line to the tree, it always sends off a mist, but never until it has turned in a direct line for the tree.

I haven't had any swarms yet, though my bees are in full formation. I don't expect to get any surplus until July, or until the cotton begins to bloom.
J. R. SCOTT.
Lamar Co., Tex., May 6.

Bees in Good Condition.

Bees are in good condition now. Also the weather is good at present.
JOSEPH CREECH.
Ontario, Canada, May 8.

Keeping Bees for Pleasure.

I have only 6 colonies of bees, which I keep for an interesting pastime. All wintered well in the house basement, which is dry and airy. They used but very little stores during the winter. I moved them outdoors the last of March, and they have been very busy gathering pollen for the past three weeks.

I have taken the American Bee Journal for two years, and must say that it is a wide-awake, up-to-date bee journal.

Ontario, Canada, May 6.

Marketing Honey—Selling Too Cheap.

I have never sold much honey, bee-keeping being a side-issue with me, as my ministerial duties and my berry-farm claim the most of my attention. I have kept a few bees for about 10 years, and now have 17 colonies, and have taken the American Bee Journal for a number of years.

There are a good many bees kept in this county, but mostly by farmers. One man has 50 colonies and another has over 100, but neither of them takes a bee-keeper.

But little, if any, honey is shipped out of the county, and there is no co-operation among the bee-keepers in marketing the honey crop, but it is "every man for himself," and as a result prices are low.

As I had only 6 colonies last spring, and the most of them were weak, and as I feared more for increase than for honey, I had very little more than the needed for my own use. However, last week I took 25 pounds of first-

A Home in Colorado FOR SALE

I have a fine Fruit-Lane of 14 acres here at Fruita, all set to fine fruit, principally winter apples, with plenty of small fruits, peaches, pears, plums, cherries, apricots, prunes, and about 700 grapes; 100 colonies of bees, mostly Italians, and about 100 fine Belgian hares that I will sell with the place. The orchard is in fine bearing, being about 10 years old, and is clean and free from weeds. The house is a good 7-room one, nearly new, with bath and water; a good new barn for two horses and two cows; good brick hen-house and two good cellars, good lawn and shade. I have a paid-up water-right with the place, with an abundance of water at all times for irrigation. I am desirous of making a change in my occupation, and will sell the place at a bargain. With the proper party the yield from the place this year will be about \$2,000. It joins up to within 20 rods of the town site of Fruita, where we have one of the best land schools in the State, employing 7 teachers. It is only 1/2 mile to the depot, churches, school and post-office, and has telephone connections with all parts of the State. This is a good, healthy climate, and good society.

We can furnish you with The A. I. Root Co's goods at wholesale or retail at the prices. We can save you freight, and ship promptly. Market price paid for beeswax. Write for our 1901 catalog. **M. H. HUNT & SON**, Bell Branch, Wayne Co., Mich.

EXCURSIONS TO BUFFALO EXPOSITION—via Nickel Plate Road.

On May 7th, 14th, 21st and 28th, respectively, at rate of \$13.00 for the round-trip from Chicago; good returning 5 days from date of sale. Three through trains daily, with vestibuled sleeping-cars and first-class dining-car service. For particulars, and Pan-American folder, write John V. Calahan, General Agent, 111 Adams Street, Chicago. Depot: Van Buren St. and Pacific Av., Chicago, on Elevated Loop. No. 8—20A2t

class honey to our county-seat, and all I could get for it was 10 cents in cash, or 11 cents in trade. They were retailing it at 15 cents. I took the 11 cents in trade, but told the merchant to whom I sold it that I did not see what the bee-keepers were thinking about to sell at such prices when it was quoted at 16 and 17 cents wholesale in all the large cities. I have been told that the prevailing price made here by the bee-keepers to the merchants is 10 cents per pound for clover and basswood comb honey, and some of them have peddled it at that price, though they selected the sections that were not well filled. Such prices do not inspire me with very much zeal to engage in bee-keeping.
J. RIDLEY.

Winnebick Co., Iowa, March 11.

Measuring Bees' Tongues.

All that is required to measure bees' tongues is a steel rule 48 hundredths of an inch marked off on one side; a glass magnifying five or ten diameters; a pair of tweezers and a darning-needle, and a dime's worth of chloroform. Put up about a dozen bees of mature age in a common mailing-case. Avoid taking young ones, as the tongues of such are not quite as long as those that are able to go to the fields. Pour a few drops of chloroform on a handkerchief and lay the cover over the bees. In about a minute the bees will be sufficiently stupefied so they can be handled, and the tongues will, from suffocation, be protruded almost their whole length.

Pick up a bee and decapeitate it. Lay the head and tongue on the steel rule just above the graduations of hundredths, face upward. With one hand exert a gentle pressure on the head of the bee, and with the other, comb the tongue out straight, using needles or tweezers in either case. The pressure on the face is to cause the tongue to protrude its full length.

Now, while the tongue is carefully combed out, take the glass, focus it on the tongue, and count off the hundredths, beginning from the ends of the mandibles or jaws, and ending with the end of the tongue. Proceed thus with all the bees in the cage, putting down on paper the exact results after each measurement. Strike a general average, and this average gives the measurement by which we go.

As a rule I find there is but very little variation in the tongue-length of the bees in any one colony. Sometimes they are all alike; but in the case of some individual bees it is more difficult to get the tongue combed out its full length.—E. R. Root, in *Gleanings in Bee-Culture*.

Thick vs. Thin Top-Bars.

S. T. Pettit, in *Gleanings in Bee-Culture*, says the idea that thick top-bars are desirable for any other reason than to prevent sagging is a delusion. The width is the important thing, and a top-bar 1/4-inch thick would be better than one thicker if it had the proper rigidity; but for rigidity he is obliged to have 1/2-inch thickness. A top-bar 3/4-inch is wasteful. That extra 1/4 inch, besides making bees more slow to enter sections, amounts to a loss of 1,000 to 2,000 or more cells in a hive. Dr. Miller replies as follows:

The mistake is in counting that the same number of bees are occupied brooding those sticks as would be occupied in brooding 1/4-inch depth of comb. The space between the top-bars is 1/4 inch, and the space between head-combs about 1/8 inch, thus knocking out half this objection at a clip. But even that half of the objection will not stand. When the weather is hot, as it generally is when supers are over the top-bars, there is no trouble about keeping up the heat; and at any time

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00.

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average (quite a good deal) the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

when it becomes cool the bees will shrink away from the space between the top-bars, and cluster on the combs above and below. Suppose you have a colony fully occupying two stories. Now put between these two stories another story filled with dummies an inch thick. Do you suppose it will take 50 percent more bees to "man" the combs than it did before? I suspect 5 percent would be plenty.

Even if the loss were all he supposes—1,600 to 2,000 cells, or 1/3 of the brood-chamber—I should still want the top-bar 1/2 deep. At one time I used, entirely, wide frames holding eight sections; and when I put on a super I put in the middle of it a brood-comb from below. The bees very promptly occupied that super, but it did not answer to leave the brood-comb there very long. If I left it long enough for the bees to begin sealing the sections, they would carry across some of the old comb, and the sections would be about as dark as the combs opposite. With 3/4 top-bars, which I used exclusively for many years, the same thing would happen to a certain extent if no slat honey-board was used, especially if the sections were left on some time after being sealed.

So if the prevention of burr-combs by deep top-bars beall a delusion—which I do not believe—and if there is a loss of 1,600 to 2,000 cells to a colony—which I am very far from believing—I still want 1/2 top-bars for the sake of having the sections so far from the brood-combs that the bees will not find it convenient to carry up a lot of black wax to spoil the snow-white sections.

The Poison of the Bee.

The inflammation and other unpleasant symptoms which usually appear after a bee-sting are often attributed to that sharp acid so widely distributed in the animal kingdom, and known under the name of formic acid. This fluid, however, has nothing to do with the swellings, its utility to the bees is of quite another character. Prof. Joseph Langer, of Prague, a little while ago, examined the contents of the poison-glands of 25,000 bees. This he found to be a clear fluid, soluble in water, tastes bitter, and has a pleasant aromatic smell, which, however, soon passes away; this scent can not, therefore, be the poison. The formic acid which gives its peculiar acid reaction to the contents of the gland is also very evanescent. The contents of the gland itself retain their poisonous properties, however, even when dried and subjected to heat. The poison is, we therefore suppose, a vegetable base, an alkaloid, as the most active poisons in the vegetable kingdom are known to be.

Prof. Langer proved that the poison has no effect whatever on a healthy skin; if, however injected under the skin, all the symptoms of bee-stings set in. Should it reach the larger veins or arteries it causes a general disorder of the system, which reminds one of snake-poisoning. The weight of the poison injected into the wound made by a bee's sting is between 2/100,000 and 3/100,000 of a grain. The largest part of this is formic acid, which is such an important factor for the well-being of the bees. This works as a means of preserving the honey, owing to its acid reaction. The bee allows a little formic acid to fall into each cell filled with honey before it is closed or sealed, and this small quantity is enough to prevent fermentation. Honey extracted from inscribed combs never keeps long unless 0.1 percent formic acid be added, which is all that is required.—Translated from the German by R. Hamlyn-Illaris, in the British Bee Journal.

Weight of Bees and Their Loads.

The following Stray Straw appears in Gleanings in Bee-Culture:

Alex. Astor reports in Revue Int. that he made 140 weighings of bees, weighing 2,300 bees in all, and he gives in milligrams the weights of different kinds of bees. From this

To make cows pay, use Sharples Cream Separators. Book "Business Dairying" & Cat. 212 free. W. Chester, Pa.

Please Mention the Bee Journal when writing Advertisers *****

I deduce the following table, showing the number of bees in a pound avoirdupois:

4054 bees just out of the cell.
3898 bees falling before a swarming colony (probably 2 or 3 days old).
2457 wax-workers.
3874 swarming workers.
4855 black workers in May-June.
5006 Italian workers in May-June.
5151 black workers in July-August.
5271 Italian workers in July-August.

According to that, the load of honey of a swarming bee is about $\frac{1}{4}$ its own weight.—[This table is exceedingly interesting—the more so, as I think it confirms very well the figures that have been given heretofore. It appears, then, that bees weigh more during the swarming season, and that wax-workers weigh the most of any. This fact is new as well as interesting. It appears, again, that in May, June, July, and August the black workers are heavier than the Italian. I had always supposed that the average Italian bee was, if anything, a shade larger or heavier than the black. Is it not possible that the black bees referred to were Carniolans, or of that persuasion? If so, there would be all that difference as indicated in the table in the relative weights, for we have come to assume that the Carniolan is the largest bee of the species *Apis mellifera*; and we have also assumed that the black bees of this country—not the brown bees—were the smallest. With regard to the amount of nectar a bee can carry, it seems to me the figures that I have seen heretofore are somewhat in excess of one-fourth its own weight. There, I have just looked it up. Yes, Prof. Koons estimates there are 4500 bees in a pound, and that 1000 bees can carry a pound of nectar, this being the fewest number to carry such an amount. According to this, then, a bee can carry half its own weight in nectar. But Prof. Koons estimates that on an average it will not carry more than one-fourth of its own weight; and this agrees with the above figures. But so far as wing-power is concerned, we know that one bee can carry one of its companions; it could, therefore, carry its own weight in nectar, providing its honey-sac would hold that amount, which is probably not true. I have dissected the honey-sac of worker-bees when they were filled with nectar, so that they almost dropped down as they flew in at the entrance. This was, at the time, about the size of a No. 4 shot, or perhaps a little larger.—EDITOR.]

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, May 7.—There is very little being done in honey at present with practically no demand for the extracted grades; several consignments on sale here for some time, without any bids being made. A little choice white comb sells in a retail way at 16c, with all other grades scarce and firmly held at about former prices. Extracted, 70c; for fancy white; ambers, 66c; dark, 55c; 5c. Beeswax, 30c.

R. A. BURNETT & CO.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from $\frac{1}{2}$ to 1 cent per pound.

C. H. W. WEBER.

BUFFALO, May 18.—Fancy 1 lb. comb, 15c; dark very dull indeed, 8c; 12c. Berries hurt sale of honey now.

BATTERSON & CO.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00.

PEYCKE BROS.

DETROIT, Apr. 18.—Fancy white comb, 14c; No. 1, 13c; 14c; dark and amber, 10c; 12c. Extracted, white, 6c; 7c; amber and dark, 5c; 6c. Beeswax, 27c.

M. H. HUNT & SON.

NEW YORK, May 3.—We report aquiet market on all lines. While the old crop of comb honey is well exhausted, still there is a demand, which has been carried by the producers, evidently, for a higher price. Values are mostly nominal now, and it is only a first-class fancy article that will sell at quotation prices. We quote: Fancy white, 15c; No. 1, 13c; amber, 11c; 12c; buckwheat, 9c; 10c. Extracted is decidedly dull, and very little inquiry. Old crop of California light amber and party white, is now being offered as low as $\frac{1}{4}$ a pound f.o.b. coast, which, of course, hurts the sale of other grades to a large extent. Beeswax is firm and sells on arrival at from 28c to 30c.

HILDKRETH & SEGELKEN.

KANSAS CITY, May 4.—Practically no shipments arriving, and very little selling. We are getting \$3.50 to \$3.65 per case of 24 sections No. 1 white; amber, \$3.00 to \$3.25. Beeswax scarce at 25c.

W. R. CROMWELL PRODUCE CO.,
Successors to C. C. Clemens & Co.

ALBANY, N. Y., May 3.—Honey market very dull. Very little call for anything but choice comb honey, of which there is a scarcity. Extracted quiet.

H. R. WRIGHT.

BOSTON, May 4.—Fancy white comb honey we quote at 17c; No. 1, 16c; No. 1, 15c; 16c. No call at all for dark honey this year. Water-white extracted, 8c; 9c; light amber, 7c; 8c. Beeswax, 27c.

SAN FRANCISCO, May 8.—White comb 14c; 12c; amber, 8c; 10c; dark, 6c; 7c. Extracted, white, 5c; 6c; light amber, 4c; 4½c; amber, 3½c; 4c. Beeswax, 26c; 25c.

The market is quiet and lacking in firmness. Buyers are holding back, anticipating liberal offerings soon. Dealers appeared before the Board of Health of this city, to receive sanction for the use of glucose in honey to prevent granulation, but the Board refused to take any special action.

National Bee-Keepers' Association

OBJECTS:

To promote and protect the interests of its members.

To prevent the adulteration of honey.

To prosecute dishonest honey-dealers.

BOARD OF DIRECTORS.

E. WHITCOMB,	THOS. G. NEWMAN,
W. Z. HUTCHINSON,	G. M. DOOLITTLE,
A. I. ROOT,	W. F. MARKS,
E. T. ABBOTT,	J. M. HAMBLIGH,
P. H. ELWOOD,	C. P. DADANT,
E. K. ROOT,	DR. C. C. MILLER.

EXECUTIVE COMMITTEE.

ERNEST R. ROOT, President.
R. C. AIKIN, Vice-President.
DR. A. B. MASON, Secretary, Toledo, Ohio.

EVGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

AN APPROPRIATION from the Ontario Government, of \$500 to be used in helping to make an exhibit at the Pan-American Exposition. Up that way they know how to get up a good show.

"DISEASES OF BEES AND LEGISLATION" is the title of a small pamphlet issued recently by Mr. N. E. France, State inspector of apiculture for Wisconsin. It treats of foul brood, its cause and cure; pickled brood, black brood, dysentery, etc. Under "Legislation" it gives the laws of Wisconsin relative to bees. It can be had free by the bee-keepers of that State.

"THE HOME CIRCLE" department is thus very kindly referred to by "Stenog" in Gleanings in Bee-Culture:

"Prof. Cook's talks for the home circle, now running in the 'Old Reliable,' constitute a most excellent feature of it. They bear largely on the proper management of children, and home conduct in general. All who have Mr. York's paper will do well to read these lines of Prof. Cook the first thing, as they fit one for what follows. For of all, we know that the writer speaks from experience, and in his daily life is an exponent of what he enjoins."

FRENCH HONEY-CARAMELS.—The Gazette Apicole, a French exchange, gives the following recipe for making caramels, which it pronounces "incomparable." Rose water, 15 grams; powdered sugar, 100 grams; fine honey, 200 grams. Mix and boil, stirring constantly, until a drop of the compound, when cooled, is hard and fragile. Pour out on a buttered or oiled marble slab, and shape the mixture into suitable pieces by means of a teaspoon. So reports Gleanings in Bee-Culture.

DR. C. C. MILLER is nothing if not a crank on the subject of roses. Of course, any one who is that kind of a crank is a delightful crank. In Gleanings in Bee-Culture he wafts this bit of rose perfume through a single stray straw:

"One rose in September is worth more to me than ten in June; so as soon as the blossoms show on the hybrid perpetuals I carefully pinch off every one except one or two of the most advanced on each bush. Then the bush is not exhausted with its June crop, so as to give no roses later. Of course, that will not do for June roses, but their stalks are cut back severely in spring, which makes the blossoms a little later, and perhaps a little finer."

GRAN HONEY-PLANT OR BELLEFLOWER.—Mr. O. O. Poppleton, of Dade Co., Fla., wrote us as follows May 1:

FIENNY YORK.—I send you today a photograph of my Cuban bee-plant, taken last December, while it was in full bloom. It grows over the porch of my house. This plant is the source of nearly all the vast amount of honey obtained in Cuba, and I am informed that it is also abundant in other islands of the West Indies; also in Mexico.

Its scientific name is *Ipomoea salsola*, common name, "Azulnido," while in English it is usually known as "Belleflower." This is one of the morning-glories, probably the most abundant bloomer of the entire genus. It is confined to the tropics, as frost kills it to the ground.

The flowers are shaped like a church-bell, are about 1 1/4 inches across and deep. It is nearly all a pure white, shading into purple and yellow in the bottom of the inside of the flower. In Cuba it blooms from about Nov. 25 to late in February. It is a very showy flower, and when in full bloom it looks, at a little distance, almost like snowbanks, especially when it runs over hedges or fences. It not only yields large quantities of honey, but seems to yield it steadily under all conditions of weather. Nothing seems to diminish the yield from it, unless the weather is such as to prevent the bees from getting out and working.

Honey from the flower is of about the same color and body as that from white clover, with a distinctive but rather mild flavor of its own. I should judge that it will rank in the general markets as between white clover and basswood honeys, not equal to the first, but better than the last.

The principal interest this flower has to American bee-keepers is the fact that it furnishes nearly all the foreign honey that competes with our product in our own markets. Those of us who have to dispose of our crops in the Eastern seaboard markets, are already feeling the result of its competition.

O. O. POPPLETON.

MRS. GEO. JACKSON, of Grand Traverse Co., Mich., is one of the growing number of very successful women who keep bees. The following paragraph from Gleanings in Bee-Culture tells something of the results she has obtained:

"In the fall of 1897 I had 18 very strong colonies, and about 900 pounds of comb honey. The bees again wintered well, and in the spring of 1898 I had still 18 strong colonies. Well, I felt, and do still feel, proud of those bees. They commenced work the first day they were out of the cellar, and worked every pleasant day during the summer, and until heavy frost came in the fall. One colony, the 'Queen' of my apiary, did itself 'prod.' During the summer we took from it *ten supers* of well-filled and nicely capped white honey, each super containing 24 pounds. It did not swarm, and we had a heavy flow of basswood honey. The other colonies swarmed early, and June 10 I had 37 strong colonies. I did not get less than two supers of honey from any colony, and from many of them four."

Mrs. Jackson says that Mr. Jackson has given up all claim to the bees, "reserving only the privilege of eating the honey." He is a wise man. Any man who has a wife that can get such results from bees as Mrs. Jackson has done, can do no better than simply to lay claim to his wife only, and then let her manage the rest. Her price is far above—well, say "\$200 red-clover queens!"

MANFIELD PARRISH'S fine decorative design on the cover of The Ladies' Home Journal for June forms a fitting introduction to a remarkably attractive issue. Among the most interesting features of this number are a double page of pictures, entitled, "Where Golf is Played," showing some of the handsomest country club houses in America; a series of curious "Love Stories of the Zoo," told by Clifford Howard; the first installment of a fascinating new serial, "Aileen," by Elizabeth Knight Tompkins; a touching full-page picture of "The Passing of the Farm," by W. L. Taylor; the queer experiences with "Some People I Have Married," by the Rev. D. M. Steele; and a vigorous article on "Women as 'Poor Pay,'" by Edward Bok. Numerous other articles of general and domestic interest fill out the rest of the number. By The Curtis Publishing Company, Philadelphia, Pa. One dollar a year; ten cents a copy.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

THE OLDEST BEE-PAPER IN AMERICA

41st YEAR.

CHICAGO, ILL., MAY 30, 1901.

No. 22.

Editorial.

The Freight-Rate on Comb Honey was left unchanged by the Western Classification Committee at its recent meeting in California. We suppose bee-keepers ought to be grateful for this, but in all justice to comb-honey producers, the rate should be reduced. Perhaps with the proper effort on their part at some future time the reduction will be secured.

Steam-Press Wax-Extractors. A late number of *Gleanings in Bee-Culture* occupies several pages discussing wax-extractors. It seems that for several years in Germany and France, and more recently in this country, wax-extractors have been in use by which the wax is pressed out by a screw-press, the press all the while being kept within steam, so that there is no danger of the wax chilling as when taken from a heated place and put in a press in a lower temperature. Some object that these steam-press extractors are on too small a scale for rapid work. Gerstung, a German editor, has invented a press to work in hot water, which he claims is better than in steam. It is possible that the solar extractor may have to take a back seat for something that will do more thorough work in getting the wax out of old combs.

Foul Brood in Michigan. Geo. E. Hilton, president of the Michigan State Bee-Keepers' Association, sends us the following concerning the foul-brood law in that State, which he desires all Michigan bee-keepers to read:

TO THE BEE-KEEPERS OF MICHIGAN.

So many letters are coming to me regarding the foul-brood law in Michigan, that I will try, through the bee-papers, to answer in a general way, and save myself valuable time at this busy time of the year.

First, the law is in operation to-day, and the inspector is appointed. I feel very much relieved. I have made four trips to Lansing in behalf of the measure, and it required all the influence that myself and others could bring to bear to secure its passage, as its importance was so little understood. I have paid out about \$30 in expenses, to say nothing of the time I have donated, which would amount to as much more. And now I want the bee-keepers of the State to take advantage of the law, and receive the benefits that may come from our efforts.

I went to Lansing last week, spending a portion of three days, and succeeded in having John M. Rankin, our State anti-brood, appointed as our inspector, and I know of no one that can better attend to the work, or who is more worthy of the position. The work

is under the management of the State Dairy and Food Commissioner, Hon. W. B. Snow, of Lansing, Mich., to whom all communications should be sent. He is in direct communication with the Agricultural College, and will inform Mr. Rankin what is expected of him.

We have but \$500 to use this season, but as the necessity of the work becomes apparent we shall be able to get more. The disease has an alarming foothold in our State, and it behooves every bee-keeper in Michigan to do his whole duty in assisting in the extermination of this dread malady.

Trusting the above will make everything plain, and save me many personal letters, I am, Very respectfully yours,

GEO. E. HILTON.

President Michigan Bee-Keepers' Association.

Mr. Hilton and others deserve the thanks of every Michigan bee-keeper, for their successful efforts in securing the passage of their foul-brood law, and also for the appointment of Mr. John M. Rankin as foul-brood inspector. Now, let all co-operate in the attempt to eradicate completely the scourge which Mr. Hilton says has already gained such a foothold in Michigan.

Other States should promptly follow the good examples set by Wisconsin, Michigan, Colorado, and some other progressive States that have been wise enough, and energetic enough, to enact laws for the purpose of protecting the bees from the deadly disease of foul brood.

Let us all hope that after the bees, the hogs, the cattle, and all other farm live-stock have been fully protected, our legislators will wake up to the importance of protecting that "best crop of the farm," the boys and girls, from the curse of the saloon. Up to the present time they are not considered of sufficient value in most States to overbalance the greed for ill-gotten financial gain.

Simmins' Method of Introduction seems to be gaining in favor. Confine the queen fasting for 30 minutes, keeping her warm, and let her run quietly in at the top of the hive, proceeding and following with a puff of smoke. This at night. Then don't disturb the colony for 18 hours.

Dzierzon and Langstroth. Some discussion has taken place in *Gleanings in Bee-Culture* between Editor Root and Dr. C. C. Miller as to the merits of these two great leaders. From the discussion it appears that neither of the two gets more credit anywhere than he deserves, and that neither gets outside his own country as much credit as he should have. The work of Langstroth is not fully appreciated in Germany, and Dzierzon is too little appreciated in this country. The

high value of the doctrine of parthenogenesis given by Dzierzon is by some fully appreciated on both sides the water, while many on this side scarcely know what is meant by the term. In Germany Dzierzon is credited with the invention of movable combs (bars being used with side-opening frames necessitating the cutting of the combs from the hive-walls at each removal), the great improvement of movable frames being apparently considered by many as part and parcel of Dzierzon's work, while Langstroth is scarcely recognized; while on this side it is apparently not generally known that Dzierzon gave to his countrymen movable combs before movable frames were invented, his bar-hives still being in use in that country.

While not taking a single leaf from Langstroth's crown of laurel, we on this side can right at least half the wrong by recognizing Dzierzon at his full worth.

Decoy for Swarms. Mr. Doolittle says in the *Progressive Bee-Keeper* that years ago he hung up dried mullen tops that had been out over winter, for swarms to settle on, and three out of four swarms chose those settling-places. For those who allow natural swarming he commends the following, which he cut out of an old newspaper:

"A good way to catch swarms is as follows: After each melting of wax preserve the residue of dirt, pollen, cocoons, etc., which is left after the wax has been pressed out, until enough for the purpose has been obtained, when you will add to it one-half pound of rosin and melt it all in an old vessel. Then having secured some old mullen tops, take an old spoon and spread some of the mixture onto one side of two or three, then keep adding more tops and of the mixture, until the whole cemented together is a fairly good representation of a swarm of bees, when you have an excellent bee-ho. When the swarming season comes on, hang your bobs on the limb of a tree or a pole in the apiary, within the reach of your hand, and of the bees also and nearly every swarm will settle on it. For something to hang it up by, put in a good, stout wire while making, cementing it in at the center."

A School for Bee-Keepers is one of the up-to-date things in Vienna, Austria. Government aid has been secured, ground purchased, and a building erected. The German bee-journal, *Bienen-Vater*, has a fine picture of the building, and another of the apiary. A chief course is to be held some two weeks, beginning in June, with a possibility of the same being repeated. Only 20 applicants will be received at these chief courses. Subsidiary courses will be held on 10 specific afternoons on different dates from June to September, allowing 10 to attend. Tuition is entirely free.

Depending Upon Bees Alone for a Living.

BY C. DAVENPORT.

I HAVE noticed that the question, "Is it safe for one to depend upon bees alone for a living?" is one that is frequently asked, and Dr. Miller has ably handled the subject a number of times, but perhaps a few words from me in regard to the matter may not be considered out of place, for I am one of the few who are specialists, that is, I have no other business or occupation of any kind except bee-keeping, and I have made a living and enough so I could stand a few failures without going to the poor-house. But my locality is a good one, and I have had nobody but myself to support, for I have never been able to secure one of those "queens" that wear dresses and other clothes, so the prospect of a crop-failure, with me, has never caused the fear of having children crying for bread.

If I had my life to live over again I should not be a bee-keeper, for I believe the work I have done to make what might be called a success in our pursuit, would, in some others, have resulted in better success financially, and also in other ways. But I am now too old to change my occupation, and it is not likely that I will ever do so. And while I should not advise a young man to take up bee-keeping as a life work, in my opinion there is no question but what a living can be made at it in a good locality, if one understands the business. There is, though, no need for a man with a family to depend altogether on bees for a living, for he should own at least a few acres where the home yard is located, so that a few cows and pigs, and a large flock of poultry, could be kept. These with 300 or 400 colonies of bees would, in a good locality, insure a living for a family, and a bank account as well.

I am acquainted with a bee-keeper who has about the above number of colonies, and his income last year was about \$1800; though this to some might be considered a small amount, here it is considered a large income, and by some would be looked upon as a small fortune. Though we are not as bad here in this respect as a man from one rival region who wrote to a firm in regard to their lowest-priced saw-mills. Soon after the information was sent, the firm received the following letter from him:

"Der Sars: I admit a goiter boy any saw-mill. Wat do yer take me fer? If I had \$300 what do yer think I wud want a saw-mill for?"

It seems that in his locality \$300 was considered enough so that any further business enterprise to increase the amount was needless. And as with this man, some may find that it costs more to secure and properly equip 300 or 400 colonies for either comb or extracted honey than they think it does; and to make a success of bee-keeping at the present time, modern hives and appliances must be used. It is so now in any business or pursuit. To succeed one must keep abreast of the times, and the profession of bee-keeping is not as easily acquired or mastered in all the many details essential to success as many imagine, for probably in few if in any other pursuits there is so much conflict of opinion as there is in ours. So many of these important details must be settled and determined individually, for the methods and appliances that work well with some, may with others in a different, or even the same, locality, be a failure.

For instance, about the worst investment I ever made in our fixtures was for 40 wood-zinc queen-excluders. Do not think that I am condemning excluders, for I use a large number of them, but they are all-zinc. I know that many prefer wood-zinc to all-zinc, but with me they are worthless.

The way I remove an excluder from a hive is to insert the thin edge of my hive-tool under it, and strip it right off. When this is done here with wood-zinc, the very thin pieces of wood that hold the zinc strips to the wood partitions are also stripped off, and the whole thing soon comes to pieces. It is the amount and character or stickiness of the propolis gathered in my locality that causes this. Even with the all-zinc wood-bound ones, the thin part of the wood frame that holds the zinc soon peels off, so that I have to make new frames; but frames can be made for them that will hold to be stripped right off, no matter how badly stuck to the hive

and top-bars they are. Of course, one could use enough care to remove any kind without injury, but I have not time for this. During the busy season I have to make things move quickly, and it is money worse than wasted for me to invest in, or keep any appliances with which much unnecessary care has to be used, or that requires needless time to handle.

To illustrate again, last season I was explaining to a bee-keeper the great superiority of hives that did not have an entrance cut in the hive itself, which allowed them to be quickly tied up, mouse, bee, and even dust tight. His reply was that if entrances were cut in the hives, and it was desired to tie them up, it did not take long to stuff in rags. It takes more time, though, than I can spend for this purpose. When a hive body or cover, with me, needs to be stuffed with rags, it soon goes to the wood-pile. Not but what they can be used so as to help secure as much surplus honey as those which are not defective, but with me the time lost in fussing with them is soon worth more than the cost of new ones. And in regard to bees themselves, I want the German, or what I call the brown bees, for comb honey. I believe I stand practically alone in this matter, but after years of experience in a large way with both races side by side in the same yard, I am convinced that I can secure more surplus white comb honey here with brown bees than I can with Italians. The main trouble I find with Italians is their determination to stuff the brood-chamber at the commencement of the flow, and I have never been able to overcome this trait. And then, after they have put anywhere from 15 to 30 pounds of white honey in the brood-chamber which should have been in sections, instead of then being willing to work in sections, they are usually determined to swarm, and Italian swarms do not, with me, do as much section-work as do the swarms of brown bees. With the latter I can secure practically all the white honey in the sections, whether they swarm or not.

But in my opinion there is as much difference in brown bees as there is in Italians. For extracted honey I prefer Italians; they will gather more honey, go a greater distance, and protect their hive and combs from the ravages of the moth-worms much better than will brown bees, and this is no small matter in my locality.

Some claim that moth-worms never injure strong colonies of any kind of bees, but this is a mistake, for the combs will be injured, and hundreds of eggs, larvae, and hatching brood, will sometimes be destroyed here by moth-worms in strong, thrifty colonies of brown bees.

Southern Minnesota.

Short-Cuts in Extracting Honey.

Read at the Wisconsin State Bee-Keepers' Convention, at Madison.

BY FRANK MINNICK.

SOLOMON says, in Ecclesiastes 1:9, "The thing that hath been it is that which shall be; and that which is done is that which shall be done; and there is no new thing under the sun." In passing through the historical rooms of our beautiful capitol some years ago, I saw the hand of an Egyptian mummy, and wondered if it had not wrought in accord with Solomon's words; or, in the words of the poet with a line of my own added,

"Perhaps this merry hand now pinioned fast,
Has labored with Pharaoh, glass to glass;
Or doffed his hat to let Queen Dido pass?"

Or handled Langstroth or similar hives, which are first-class.

But whatever may have been, or whatever of lost arts are buried in the sediment of the Nile, or wherever they may be, we are where we are. Historians look into the past, poets into the future, but we have to deal with the present, so let us get down to business.

Very often the shortest way across is the longest way around, but I wish to call to your minds a few of the short-cuts that I have discovered in reading a few works on bee-culture, and in the 20 short years that I have made bee-keeping a means of gaining a livelihood.

In the first place, it is very desirable that the bee-yard be laid out in such a way that the backs of the hives are toward each other, and the rows far enough apart to leave plenty of room for the "honey-carriage," and a space to work in where scarcely any bees are flying. It is also well to have the extracting-room lower than the yard, for one can wheel very much more down hill than up.

After handling many different sizes of combs I have settled down to what the "father of American bee-keep-

ing," our beloved and lamented Langstroth, considered the very best—his 10-frame hive, in brood and extracting departments. I have worked my winter repositories (which are cellars) into extracting-rooms, and they are very cool and pleasant on a hot summer day. I have discarded screen-doors and ventilate through screen-windows. Bees will not accumulate on a wooden door and rush in with you by the thousands to annoy.

Place the extractor on a platform from two to 4 feet high, and dig a pit so that the honey goes by gravity from the extractor through the strainer to the keg. My strainer-box is made after the Rambler pattern, which is a honey-tight box with a roller on both ends near the top. The cheese-cloth which I use for a strainer is rolled up on one end and stretched to the other, as it becomes clogged. It is rolled by means of a ratchet-wheel on each roller, held in place by a single spring extending from one wheel to the other. I have also a tin strainer above the cheese-cloth, which catches all the coarse stuff.

For an uncapping-can I use a 200-pound honey-keg with the head out. I take a clean sugar-barrel hoop, and bend and nail it together so it will drop down into the bottom of the keg; then make another one that will fit inside of the first one: place unpainted wire window-screen on the larger hoop, pressing the smaller one down into it, which when strengthened with a few pieces of lath makes a fine strainer for the uncapping-can; and a hole made in the bottom allows the honey to drain out.

For a frame to hold the comb while uncapping I use a strip across the top of the keg 1x2 inches with a nail driven through each end, between the hoop and stave, to hold it steady; but before I nail it I drive an 8-penny wire-nail about 6 inches from one end from the upper side, for a point on which to hold the combs while uncapping. Now this point on which turns my fortune or misfortune, I sometimes think! holds the frame at almost any angle desired without slipping, and I can reverse it. All these motions which I necessary in uncapping are accomplished with one hand without lifting the comb.

I know of no better uncapping-knife than the Bingham & Hetherington. I used to lay the knife on the strip on top of the keg with the handle projecting over the edge, but hereby hangs a tale. The one who uncaps is called the "shaver," and I was acting in that capacity one day, when, in handling a heavy, slippery comb I let it drop on the projecting handle, which caused it to jump at me like an animate thing; as poor as its aim was it made a "short cut" in my ear, and drew forth rich, royal blood. So now I drive a small nail part way into the end of the handle beside the shank, and hang it inside of the keg.

The Porter bee-escapes are a great invention. I try to get them on at least 24 hours before I wish to begin extracting, then usually I can go out and run the supers in like so many bricks. I try to have enough to keep us running all day, so I put the escapes on another lot immediately so that they will be ready to extract the next morning.

Now comes the work which is to me the pleasantest part of bee-keeping. With veil laid aside, sleeves rolled up, and my honey-kegs previously tested with boiling water, I am ready for a big day's run. As the combs are uncapped they are placed on the platform in a box with a tin bottom, from which an active, careful boy runs them through a Cowan extractor. The empty keg is placed on scales under the strainer-box, which will sink at the desired weight, and cause the honey-gate to close automatically, by means of a stick reaching to the honey-gate from the keg. The keg is quickly removed and replaced by another, and so the work goes merrily on, and I am content.

Shall Bees Be Taxed?—A New Yorker's Opinion.

BY FRIEDEMANN GREINER.

IT is my opinion that every patriotic person, and all good citizens, should be willing, nay, anxious, to pay their just share of taxation, bee-keepers included. If our patriotism makes us liberal only in the expenditure of money used for fire-crackers, beer and whiskey, that we might celebrate the anniversary of the Declaration of Independence worthily (?), or perhaps the victory of the Republican party, or any other political party, then our patriotism is not worth much, and leads us astray. If our patriotism does not prompt us to come forward with our treasures, our stored-up papers, mortgages and notes, and demand that we are justly taxed for all we possess, as a reciprocity act for the protection we enjoy, then we would better not

make much ado about our patriotic feeling. I am sorry to say that a great many people, even those of high rank, try in every conceivable way to hide their possessions before the eyes of the assessors and tax-collectors.

I am not sure that taxation will ever be equitably adjusted. The situation to-day is practically about the same as in the many centuries gone before. History shows that the poor class, the people of little influence and means, were always controlled and oppressed by the strong and rich class, which in turn again gave rise to the so-called revolutions. In other words, the common people would endure about so much, but when the pressure became too great, then they kicked. Of course, we hope that a Christian spirit will so penetrate the heart of each individual, and the masses, that this earth will become more heaven-like, and that selfishness will be driven out; but much water will probably flow down the Rhine before we reach this state of things. Let this be as it may. I do not wish to sneak out and avoid being taxed on my bees. What I do object to is, to be picked out of the large number of wealth producers and owners as the only one to pay taxes. I am in favor of having all kinds of property taxed, have brains taxed, etc. We did not succeed in having a national income-tax law passed—it was declared unconstitutional. Let us try it again—it is a just and wise measure, just the same. Those that have shall give, ought to give!

If I am going to be taxed on my property am I not justifiable in demanding that my neighbors shall also be taxed on their property? To illustrate I wish to say: One of my neighbors has six fine horses; their market value is \$600; nothing said of the single and double, light and heavy harnesses, wagons single and double, carriages, reapers, binders, etc.; he has 20 head of cattle, their market value \$500; then he has 100 sheep with a market value of \$800 dollars; a herd of swine, valued at \$100—all in all, his stock has a value of \$2100. Let it be understood that at an open sale his stock would probably bring that amount of money, at least. But a few days ago I asked him how much tax he paid on this nice investment. Well, what do you think? *Not one red cent!*

I am a bee-keeper, principally. My stock of bees consists of 150 colonies. At an open sale they might bring \$300, no more. Of course I would not sell them for that, not even for twice that amount. Besides the bees, I keep one horse and two cows, valued at \$150, which concludes the list of my stock. In all it represents in value \$450. So as not to be called unfair, I will put it at \$700. Some years ago when the assessor came around he was much inclined to assess my bees (and I had but about 65 colonies at that time). Of course I objected. Pray, why should I be taxed on my \$700 investment, while my wealthy neighbor is exempt on his \$2100 stock investment?

When all other personal property is enlisted on the assessor's list and lawfully taxed, then I will cheerfully consent to have my bees listed, also I understand in some States, in particular in the South, a tax is levied on watches, pianos, other musical instruments, carriages and stock of all kinds. Of course, where this is the case bees should not escape.

But there is another standpoint from which taxation of bees may be viewed. The cane-sugar interest in the South, and the beet-sugar interest in the West and North, are fostered by the Government to such an extent that even a premium or subsidy is paid to sugar manufacturers on every pound of sugar produced. Honey is sugar. Why do we bee-keepers not receive a subsidy on the honey we produce? A great deal of honey goes to waste in the flowers year in and year out. It can not be said that all honey is gathered until there are about 10 colonies kept to every square mile. The honey, if left in the flowers, does no one any good. Uncle Sam ought to encourage bee-keeping, to the end that all this honey might be gathered and saved, instead of taxing bees out of existence.

And, finally, there are thousands and millions of blossoms that need fertilizing every year. Many fail to set fruit for lack of pollen-carriers. More bees, even if they gathered no honey for us, would be an advantage to the fruit interest in most localities, and *should be kept* for the sole purpose of fertilizing fruit blossoms. For this service the bees ought to receive pay, and protection, or rather the bee-keeper ought to receive from the Government a certain amount premium, say 50 cents, or more, for each colony kept, instead of being taxed for them. This idea is not a new one, by any means. The people of the middle age valued the service the honey bees rendered, and did pay a premium for keeping them. I believe I mentioned this

fact several years ago in a longer article on the history of the bee.

Great interest in bee-keeping was manifested in a later age by that great king and statesman of Prussia, Frederick, living during the 18th century. His order was, that every minister of the gospel in his kingdom, every order of monks, and all monasteries, must keep a certain number of colonies of bees. Every renter of crown lands paying 150 thaler rent had to keep 10 colonies; those paying higher rent 20 colonies. For every colony less than that number five thaler penalty had to be paid. Each farmer (bauer) had to maintain an apiary of four colonies, from that number down to one colony, according to the number of acres of land he owned. Failing to meet these requirements, about 50 cents had to be paid for every colony not kept. On the other hand, *so cents premium was paid for every colony kept over and above the required number!* From this it will be seen that Frederick must have been convinced that bee-keeping offered many advantages, and produced great benefits. In this understanding he was far ahead of many of the leading statesmen of the present day, who can often see nothing but evil resulting from the keeping of bees, and desiring to rule them out and almost exterminate them.

Artificial Swarming or Dividing for Increase.

BY C. P. DADANT.

CHARLES DADANT & SONS—I think I have seen somewhere that you practice artificial swarming, exclusively. Do you still think it best, and can you secure as much comb honey? It would certainly be much more convenient if as good results could be obtained.—D. C. ROBERTS, Colorado.

Yes, we practice artificial swarming exclusively, though we do not call it by that name. We call it "division of colonies," because it is not anything like swarming. True artificial swarming is done by removing a swarm with the queen in a forced way, either by drumming the bees out from one hive to another, as formerly practiced with the box-hives, or by shaking enough of the bees with the queen into a new hive.

I must say, however, that if we were practicing bee-culture for comb honey with the usual eight-frame hive, such as is recommended by many bee-keepers, we should be far from practicing artificial swarming, but would instead try to devise means to prevent the natural swarming in the limit of our power. From repeated acknowledgments of comb-honey producers who use small hives, I have concluded that this method of bee-keeping produced rather too much increase in ordinary seasons, and that the desideratum was a method by which less increase could be had.

By our methods, we produce extracted honey almost exclusively, with large hives, always supplied with a sufficient amount of empty comb to prevent the desire of swarming, except in extraordinary seasons. So when we desire increase, usually only in sufficient amount to make up for winter losses, in each apiary, we follow the artificial methods.

As to the production of as much honey with a colony that has been divided by any manner whatever, either natural or artificial, as with a colony in which all the bees remain at their post, that is out of the question. The bees that are taken away, or that leave with a swarm, go to making that swarm prosperous, they harvest honey for its brood, and for the building of its combs, and, while doing that, they surely can not be expected to produce surplus honey. But if you are in a location in which two crops may be expected, some six weeks or two months apart, and if the second crop is a very safe probability, then what you may lose in the first crop, by dividing, will perhaps be more than repaid by the product of the extra colony which you have brought into existence. You are exactly in the position of a man who is bringing up a family. While his children are small they are a strain upon his energy, for he must support them, educate them, train them to the duties of life; but when they are grown, they may prove a very great help instead of a drain upon his resources. If you begin the season with 25 colonies of bees and seek no increase, you may have a very fair crop, but if you double their numbers, though you will have no crop during the early summer, the fall crop will probably be double what it would have been had you depended upon the original number of colonies for your supply.

There are many methods of making divisions or artificial swarms. Nearly every writer describes his own plan, and they are all good, in a greater or less degree, if they

follow the first principles of the trade—of leaving colonies queenless the least possible time.

With the new methods of queen-rearing, among which the Doolittle method stands conspicuous, it is not very difficult to rear queens from the very best mothers to supply all swarms made. Or, if this be thought too difficult, queens may be bought from reliable breeders, especially in the South, for a small price. Thus swarms may easily be supplied with very good, choice queens, and little time is lost.

The plan which we follow, and which proves the most economical, is to make our swarms, or take our increase, from the colonies which are not likely to give any surplus. This, of course, applies only to an apiary in which the colonies are not all intended for forced increase. If we must have increase at the exclusion of everything else, then let us use every colony of sufficient strength to further our purpose. But if we want an increase of say only one-third, we will aim to leave the most populous colonies intact, taking the brood and bees from colonies which have bred up too late to make a crop. This must not be understood to mean that every weak colony may be divided, for there are sometimes colonies of bees which fail to breed up, from divers causes, and which remain weak till after the honey harvest. These are of no value, and must be completely taken out of our reckoning.

But we have colonies of bees that breed up promptly and plentifully at the opening of spring, and begin the harvest with as full a force of field-workers as it is possible for them to have at any time. On the other hand, there are colonies which having been delayed in their breeding by different circumstances, are still quite prolific, and find themselves with a large amount of brood, but with less field-workers ready for the harvest. These, in other words, are behind-time for the harvest, and it is to them that we look for the supply of brood for our divisions. There is nothing lost in the way of a crop by dividing them, for they would only just begin to build in the boxes by the end of a harvest, and the brood and bees that they can furnish will give us quite a good many "swarms" that will have enough to make preparations for the second crop. Thus, if there is any chance for honey, our best colonies will harvest it, and the secondary ones will give us the increase.

But if we breed our own queens, no other considerations should deter us from using the very best colony for breeding the young queens. Prolificity and hardness first, color and breed next, should be our standard. Gentleness is also a consideration. But if we breed mainly from pure Italians this quality will be a matter of course with every one of our best colonies.

A vigilant eye must be kept on the divisions. Until they show a good queen laying plentifully, and the combs are all built, they should not be left to their own devices more than a week at a time.

In this way only can we expect to succeed.

Hancock Co., Ill.

"Long-Tongued Bees—Fad or Fallacy, Which?"

BY E. R. ROOT.

ON page 293, I find an article by Mr. G. M. Doolittle under the above heading. "Of late years," says Mr. D., "some of our bee-papers start off with some new idea, or some old one revived, and in a little while the heads in all beedom seem to get twisted. . . which, a few years later, is dropped, with hundreds and thousands of hard-earned dollars wasted over the hobby or fad."

A thousand dollars—that's a big sum; and thousands of dollars—that's bigger yet. I do not recall any fads that have been dropped that have cost anywhere near such sums. Reversible frames? We sold, perhaps, more than any one else; and yet we did not sell, all told, \$300 worth of them. Self-hivers? We sold about \$10 worth. But we must have some failure fads in order to get those that are a success.

Did Mr. Doolittle never ride a hobby, or push a fad? Well, let's see. Did he not champion wide frames for sections about 17 years ago? And now they are used by very few, including Doolittle. Was he not one of the very first who started the fad for tall sections? Did any one waste thousands of hard-earned dollars on them? I can not recall one. He started the fad for rearing queen-cups, and a very good fad it was. Did any one waste any hard-earned dollars over that? But the fad may be dropped for drone-comb queen-cups. He helped boom, years ago, in his pamphlet, "The Hive I Use," the Gallup hive; and some of his followers, as I happen to know, wished afterward they had not followed him, because they had on their hands

a lot of odd-sized hives. But now Mr. Doolittle says the Langstroth is just as good as the Gallup, and has the advantage of being regular.

And that reminds me that Mr. D. has decried other fads which he has since adopted. He condemned, for instance, thick top-bars, on the ground that he wanted bur-combs as "ladders" to enable the bees to climb up into the supers; and now he is recommending thick top-bars! If I mistake not, he once protested against the introduction of comb foundation, but is now using it, and sanctions its use. Prominently among those who pushed the fad for yellow or five-banded bees was Mr. Doolittle. If there is any fad that has cost bee-keepers a few dollars (not thousands), and for which there may have been little or no return in honey, it was the rage for golden Italians; and Mr. Doolittle is still pushing them. If I mistake not, I do not say there is anything wrong in selling them. If one wishes beauty, he has a right to pay for it, and the breeder to sell it; but when Mr. Doolittle condemns others for pushing the fad of long-tongued bees—bees that give a promise of bringing in more honey—he should not forget that there may be others who may be equally honest in advertising and selling long-reach bees.

He apparently questions the propriety of charging \$10, \$15, or \$20, for queens. If so, it is wrong for him, but perhaps in a lesser degree, to charge \$5.00 for his best queens. It may be that no single bee is worth \$25. I have no quarrel with any one who so thinks. I know this: We refused an offer of \$25 for a daughter of our best breeder. If it is right to sell stallions, Jersey bulls, dogs, and roosters of high blood, at big prices, it is awfully wicked to sell queen-bees at ten and twenty-five dollars? Certainly not; for Mr. D. has said that the queen is the pivotal center of the colony; and in the same way an *extra-good* queen is the pivotal center of a whole apiary.

He quotes Stenog, in "Pickings," as saying that no one claims that the long-tongued bees would be any better except on red clover, and then goes on to say if this is correct "then these long-tongued bees are of no special advantage to me nor to two-thirds of the acreage of North America." I never claimed that the long-tongue bees would be useful on red clover alone. The fact is, there are other honey-plants that have deep corolla-tubes. I refer especially to the *Composite* family. Then there are certain corolla-tubes in the heads of alsike that are too long for the bees to reach to the bottom; and there are certain tubes of even white clover that are somewhat long for the tongue-reach of the average bee. If there are other honey-plants that have deep corolla-tubes, then practically all of Mr. Doolittle's argument falls to the ground. He certainly knows that the flora of different localities of the United States is decidedly different, especially in the South; and he must not judge the whole United States by the vicinity in and around his place of residence in Onondaga County, N. Y.

He says, further, that he finds breeders in the extreme Southern States, such as Florida and Texas, advertising long-tongued queens, "just as if those long tongues were a great desideratum for that Southern country." Why, Mr. Doolittle, don't you know that most of the Southern-bred queens are sold in the North? Can't you see, for instance, how a manufacturer of stump-pulling machines, located on the prairies of Illinois, might sell such machines in localities in other States where such machinery would be in demand?

The quotations Mr. Doolittle makes are, I find, from one of Mr. Hutchinson's advertisements, from some of my own writings, and from a statement or two in the American Bee Journal. Right on the heels of these he says: "To give misleading statements, or those that are actually false, is something that our bee-papers of the present day should not stoop to do—even when the motive of gain prompts the advertisers." Why, Mr. Doolittle, is it possible that Mr. Hutchinson, the editors of some of the other bee-papers, and all these other brethren whom you have quoted, are putting out "statements".... that are actually false, and "stooping" to unfair methods simply for "gain"? I can not think you believe that. They may be misled; they may be mistaken; they may be wrong in their opinions; but falsifiers for gain, never.

You say there are times when it is necessary to "call a halt." I partly agree with you; but it seems to me, Mr. Doolittle, in view of what I published on page 295 of Gleanings, that you are somewhat late in the day. After making all those quotations, and putting them in such a way as to leave the impression before the average reader that those of us who sold long-tongued stock had quite lost

our heads, you might, in all fairness, have given other quotations from the same writers that hold up the danger-signals. For example, on page 295 of April 1st Gleanings, I said:

"There is danger that many who get queens of this blood (long tongue) will be disappointed, and in the end the whole business be condemned.... It is only proper to sound a note of warning.... We are not positively sure that the amount of honey a colony will gather is in direct proportion to the length of the tongues of its bees.... In any case, let us not lose our heads."

Again, on page 401 I published something more in the same line. I did not give these editorials because I thought it was necessary to call a "halt," but only to draw attention to certain phases of the question that were liable to abuse, and to prevent, if possible, probable disappointment.

In conclusion, let us bear in mind these facts: That red clover is not the only plant, by any means, that has long nectar-tubes. Second, that, if we succeed in getting long-tongue stock, we shall have bees that will get more honey out of alsike, as well as more honey out of red clover. During the seasons of heavy rains, when the clovers have a stocky, vigorous growth, I have seen the corolla-tubes of alsike as long as the tubes in ordinary red clover in common seasons, and I have seen the nectar-tubes of white clover—that is, the longest of them—too deep for the average bees to reach the bottom of.

I desire to say that I believe Mr. Doolittle is honest in his position; but he has allowed his prejudices to warp his judgment, I fear. I bear no ill will toward him, and hope he does not toward me.

No. 5.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

(Continued from page 295.)

"Now, Mr. Bond," I said, after returning with him to the hive chosen as our object lesson, "right here is a practical illustration of what may be accomplished in the direction of success in bee-culture. This colony has done wonders so far this season. In fact, it has stood first-rank ever since I first started it with its present queen."

"Bee-books tell us that a queen should be superseded the third or fourth year, because at that age queens begin to decline in egg-laying power. I have seen this seemingly orthodox deliriance asserted, re-asserted, and elaborated in the bee-papers by bee-keepers whose orthodoxy one would scarcely venture to call in question. But neither bee-text-books, bee-papers, nor leaders in bee-culture, are entirely reliable in all things; owing, however, to the fact that many things come to our notice by practical experience and observation, as we pursue each his own theory or plan, that are unique in the sense of being new, or without precedent. My experience with this colony for three years proves that this assertion, which may seem to some like an unjust aspersion, is neither rash nor egotistical."

"Well, to illustrate: I took from this hive, this morning before you came, four supers of 28-one-pound sections each, all well-filled and beautifully finished, and nearly as white as snow. The fifth super—the one I took off a little while ago—is also full of honey; but, as the sections are not all sealed over, I leave it on the hive until the bees complete their work in it. But, in order to provide honey-storing room for them I shall give them a fresh super directly."

"Now, you see, here is a honey-yield from this one colony of five supers, or 140 pounds—all white clover honey. And, the white clover yet being in fairly good condition, there is a prospect of at least one more super being filled and finished; making six in all. Then there is the late honey to come in yet, from which they may fill another super for me, and store from 30 to 40 pounds for themselves to winter on."

"Excuse me, Mr. Gehring, for expressing my opinion, but that's about the fishiest honey-story I have ever heard."

Mr. Bond was leaning against the apple-tree under which was the champion colony when he made this slangy remark. When I turned to look at him in order to interpret, if possible, the expression of his face, I saw that he had removed his bee-veil, with his hat, and was I thought rather nervously mopping his jovial face with his red pocket handkerchief. It was evident that he had quite forgotten his previous precautions against danger. There were no angry bees about just then, however, for I had not yet opened the hive, but was standing near it with my

frame-prying instrument—an old chisel—in one hand, and smoker in the other. I saw a merry twinkle in my friend's blue eyes, but otherwise he looked supremely unconscious of having said anything at all funny or improper.

"Mr. Bond," I said, "I don't blame you for making that remark. But my family and one or two of my neighbors know that what I have stated is true. Besides, here is another evidence—come here and see."

Mr. Bond hastily replaced his hat and readjusted his bee-veil before he complied. I then said, pointing to a card which was tacked to the inside of the cover of the hive: "On that card, Mr. Bond, you can read a complete record of this colony up to date, from the time it was put into winter quarters. At the top end of the card you see the figure 4, which denotes the number of the colony."

"Why don't you put the number on the front of the outside?" queried Mr. Bond.

"Because I think it is better to number the colony instead of the hive," I replied. "When a certain number is once painted on the outside of a hive I can't very well change it to another number, though I may have the best of reasons for wishing to do so. I know of excellent beekeepers who do paint the number on the outside of the hive, and they have the right so to do. But I think a better way would be—if they must have the number on the outside—to tack pieces of tin with the numbers painted on them on the front of the hive; then it would be easy to change them from one hive to any other when occasion required it."

"Your idea looks reasonable and sensible to me," remarked Mr. Bond. "But," he continued, "will you please tell me what kind of an occasion would require the change you speak of?"

"One such occasion would be, when the colony casts a swarm," I answered. "Take, for illustration, the swarm we have just lived. The hive it came from is numbered 9, on the card inside the cover. That number designated the colony, or more correctly, the queen. But the colony left the parent hive, and the queen went with it; hence, I take the record-card from the old hive and tack it inside the cover of the hive the swarm is in. In that way I keep track of the mother-queen as long as she lives, without confusion, and with the least possible trouble. But there is another reason why I transfer the number from the old to the new hive, which I shall explain when we get back to it to look after that drone-brood, and to do one or two other things that will be found necessary, I think, within a week—I don't think we can more than finish the lesson I have for you here this afternoon."

"Why, you don't intend to keep me here till dark, do you?" anxiously inquired Mr. Bond.

"No," I answered. "And that is just the reason why we can't finish the lesson to-day. You see, I make it a rule in my apiary-work never to molest my bees, in any way, after sunset."

"That's queer," remarked Mr. Bond; "I had a notion the night-time was the best to monkey with bees. My father thought so, I'm sure, for he never touched a hive during the day, except to hive a swarm."

"That merely proves that you and your father knew nothing about the nature and habits of bees," I replied. "I know lots of people who think a cloudy day is a better time than a sunny day, and a rainy day the best of all days to monkey with their bees, as you style it. Well, they are all wrong; and for the same reason just stated."

"The fact is, Mr. Bond, the very best time that can be chosen when any kind of a tedious or complicated job is to be done in the apiary—such as putting on or taking off supers, looking for queens or drone-brood, or exchanging and interchanging brood-frames—is between sunrise and noon on a clear, warm day. The bees are then nearly all busy at their work—a large number of the workers out in the fields. Hence, there are less stings and less labor for the manipulator, and less annoyance for the bees. There is only one exception to this, when regarded as a standard rule, and that is, in the case of robbing going on in the apiary. In that case all regular work among the hives must be suspended until the fracas is settled, and everything is restored to its normal state in the apiary. I will tell you more about robbing and robbers some other time. We must hurry and attend to the lesson in hand."

"Well, you can see that this record-card indicates the age of the queen, and that she is full-blood Italian. It also shows that she is clipped."

"Clipped?" queried Mr. Bond, doubt and wonder in the tone of his voice as he spoke the word. "I don't understand what you mean by that."

"I suppose you don't," I replied, "but I haven't time

just now to explain. Besides, should I proceed to do so I would probably forget where I am in the course of our lesson."

"Well, the next thing the card shows is the interesting fact that the colony had sealed brood on several frames in February; and the next, that it cast a large swarm April 12; and the next, that, before the end of the month the colony was doubled up."

"What's that?" interrupted Mr. Bond, eagerly, coming a step nearer.

"Never mind now, Mr. Bond; it's quite a little story, and a very important thing to know—but I'll have to put you off for a full explanation because it's getting late."

"What I am trying to get at in an orderly way is that proof which I mentioned concerning the honey-yield from this hive. But first—lest you lose a part of the lesson this card teaches—notice, please, the next items on record:

"April 20: Storing white-clover honey in the frames." Following that item you see here a record of dates when the five supers were put on, successively.

"Another thing: Please notice there is a little card on this end of this super"—directing Mr. Bond's attention to the super which I was preparing to remove from the hive when the swarm interrupted us.

"Well, on this card, as you see, is the number of the colony; and next, the number of the super in the order it was placed on the hive. The other four standing in the honey-house are marked in the same manner as this."

"This is the special proof I wanted to direct your attention to in order to satisfy you that bees can, and do, perform wonders in honey-gathering when they have a first-class chance."

"What do you call a first-class chance?" inquired Mr. Bond.

"Now, you've asked a hard question," I replied. "A hard question in the sense that a full, comprehensive answer would cover nearly the whole range of successful bee-culture. I can, therefore, give you only a crumb, as it were, of the whole loaf."

"One factor in the first-class chance, in this particular case, was, an uncommonly rich growth of white clover, yielding nectar very profusely and continuously for a long time. And another, plenty of young bees in the hive to gather it; in this case not less than 40,000 before April 12, and thousands more crawling out of their cells every day."

"But the bee-keeper also has a share in the first-class-chance program, if he knows his business and attends to it, and that is, he must know exactly when to give the colony supers; and he must watch very closely to be sure that they never lack honey-storing room above the brood-chamber while the honey-flow is on."

"These are, I think, the main points. But numerous other things are important also, which, if ignored, or neglected, or not recognized, will cut an astoundingly large hole in the honey crop, whether the crop is from one or 50 colonies."

"Do you put all the supers, needed by a colony, on at once?"

"I glanced at my friend sharply, when he asked this question, to see whether he was in earnest or in fun. Satisfied that he meant it seriously, I answered:

"No, indeed, Mr. Bond. I put one on first. When that is about full, and I see that the bees are sealing the sections over, I take it off and put an empty one in its place, replacing the full one by putting it on top of the other. Thus I continue to put on supers as needed, Mr. Bond."

(To be continued.)

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editor.)

Perhaps in a Starving Condition.

I have wintered my bees all right, but I have noticed for several mornings that the full grown young bees come out until the ground in front of the hives is covered with them; and they won't go back to the hive, but crawl around until they die away. These bees must either come out at night or very early in the morning.

ILLINOIS.

ANSWER.—It is possible your bees are in a starving condition. If you find no stores in the hive, feed at once. Sometimes a colony swarms out in spring because short of stores or for some other reason, and if the queen does not go with them they return to the hive leaving the young bees crawling about on the ground. The most you can do is to see that they have stores, and keep the hive as warm as possible by shutting up any cracks and allowing entrance for only a few bees at a time.

Carrying Queen-Cells a Distance.

Can queen-cells one or two days before hatching be taken three or four miles if left on the comb? Have you ever tried this?

ILLINOIS.

ANSWER.—Yes, I have tried it successfully a number of times. I have taken to an out-apiary a queenless colony with a good queen-cell on each frame, put each frame with its adhering bees in an empty hive as a starter for a nucleus, and obtained good queens thereby. I suppose, however, you mean to take the queen-cell without bees. That I have also done occasionally with success. The cell should be well advanced, and must be kept warm and not subjected to severe jarring. Pack in cotton in a little box, and carry the box in the vest pocket or some pocket close to the body so it will not chill.

Poisoning a Neighbor's Bees a Crime.

1. When I cook and prepare poison like Bordeaux mixture, etc., for my plants and shrubs on my own property, and my neighbor's bees come and eat it, and are killed thereby, can I get into trouble for it?

2. When my neighbor's bees come and rob mine, kill them and take their honey, and I in a chemical way kill the robber-bees on my own property, is there anything wrong in it when I thus protect my property?

ILLINOIS.

ANSWERS.—1. The man that cooks poison that his neighbor's bees may get is cooking trouble for himself, most decidedly. The idea that a man can do wrong to others just because on his own property is a pernicious mistake. If a man comes on my property that I don't want there, he has no business there, and I may order him off; but if I shoot him because he doesn't go I'm sure to get into trouble. Still more have I no right to destroy my neighbor's bees when they come on my property, for bees have a right wherever they can fly, and if I put poison where they will take it I am responsible. There is, however, no danger in spraying plants and shrubs unless they are in bloom, and an intelligent man will understand that it is of no use but a harm to the plants to spray at that time. When not in bloom, there is no danger to the bees, because the bees visit the plants only when in bloom. Of course if the poison were sweetened the bees would visit them any time, but the sweetening would be of no use to the plants, and a man that would sweeten the poison for the sake of poisoning the bees ought to suffer the full penalty of the law.

2. Most assuredly there would be great wrong in it. If your bees come to rob my bees, it is not your business to keep them away, but it is my business to manage my bees so that no other bees will rob them. If I leave honey stand-

ing around so as to start robbing, then I am to blame and have done a wrong to myself and to you. If I have weak or queenless colonies, I must protect them or unite them, so robbers will not trouble them. Set it down as a fixed principle that if I allow your bees to rob mine, I am the one to blame, and it is a damage to you to get your bees in the way of robbing, and if I then try to poison your bees I am stooping to so mean a thing that the law ought to handle me pretty roughly.

Extracting Propolis.

I have quite an amount of propolis scrapings on hand. What is the best way to extract or melt it?

WISCONSIN.

ANSWER.—I suppose your object is to get the beeswax out of it. I'm not sure I know the best way. I once took a dripping-pan filled with it, put it in the oven of the cook-stove, and when all was heated for some time poured or dipped off the wax. Possibly if water was added before heating, the wax would rise to the surface and the propolis sink to the bottom. Then when cold it would be easy to lift off the wax.

Simpson Honey-Plant in Kansas.

Would the Simpson honey-plant do any good in this dry climate? The climate does well here.

KANSAS.

ANSWER.—Very likely it will grow well enough, but it would be worth while to sow it in waste places only. It is probably not held by any one now that it would pay to occupy tillable land with it.

Management for Increase.

I have six colonies of bees which I want to increase to nine, and not allow them to swarm. Three are black and three are Italians, and I want to increase the Italians. My plan is this: Drive the bees with their queen from the Italian hives to new hives with full sheets of foundation, and place on the old stand, and place the old hive in the place of one of the black colonies, removing the colony of black bees to a new place. Do you think this is a good plan for dividing? Do you think it will keep them from swarming?

MINNESOTA.

ANSWER.—Yes, the plan will work. The change should not be made late in the day, lest so few bees enter the hive of brood that it be chilled. Do it early in the day, or still better at the time the bees are out for a play-spell. It would, of course, be better if you could give a queen or queen-cell to the queenless hive, for only field-bees are there, and they are not the best to rear a queen. If moved, however, at time of play-spell, there will be some young bees. If done early in the season (and it would not do to wait late for fear of swarming) there is danger that the removed black colony will soon become strong again and swarm. It will help to prevent this if at the time of removal you shake off into the queenless hive all the bees from three or four frames. If you leave them to rear their own queen, these young bees will be an advantage in that regard. But there may be danger of swarming from the queenless hive when the cells mature, so you might cut out all cells but one.

“The Hum of the Bees in the Apple-Tree Bloom” is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best beesong yet written by Mr. Secor and Dr. Miller. It is, indeed, a “hummer.” We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

The Chicago Convention Picture is a fine one. It is nearly 8x10 inches in size, mounted on heavy cardboard 10x12 inches. It is, we believe, the largest group of bee-keepers ever taken in one picture. It is sent, postpaid, for 75 cents; or we can send the American Bee Journal one year and the picture both for \$1.00. It would be a nice picture to frame. We have not counted them, but think there are nearly 200 bee-keepers shown.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

ACTIONS OF BEES AT SWARMING-TIME.

And so B. Ginner wants to know if bees pile up in front of a swarming hive in weight enough to touch off a mechanical arrangement to sound an alarm. Bees have forty different ways of swarming. I should not be surprised to see several ounces cling together on the ground in front; but once in fifty times would be sufficient to expect it, I think. Usually the downy young bees very recently emerged are mostly swept out in the rush; and many of them crawl around awhile before they can get the use of their wings. Machinery would have to be made pretty delicate to spring with their weight; but I guess the thing is possible. If B. G. will rig a second entrance somewhere about his hive (say in the rear end of the bottom-board), I think he can get all the power he needs by means of it. The idea is to have a long crack there almost wide enough to let out bees, but not quite, and a swinging gate on which the joint push of several dozen bees could be utilized. At ordinary times a bee doesn't want to get out except at the habitual place; but in the usual forms of swarming the sentiment seems to be any way to get out, or any where. Page 283.

THE LAYING CAPACITY OF QUEENS.

That Langstroth experiment on page 248, where queens are made to drop eggs on a black cloth—"some thirty, some sixty, and some a hundred fold," and the colonies turn out accordingly three months later—it is striking and instructive; yet there is danger of predicating far too much upon it. The queen that dropped only one egg may have been just as good a queen as the one that dropped twenty. It is not only possible, but probable, that each of the queens, with the exception of the first, was laying at just about the rate that the workers were able to care for the eggs. If I am right, no queen (in the season) will lay much in advance of the wishes of the workers. Far be it from me to wish to nullify all the conclusions of the paper referred to. Two things remain after we have made all proper allowances: Some queens will not keep up with the reasonable requirements of a fair colony. To supersede them is of course just the proper thing to do; only don't make mistakes about the facts. The other thing is that some few queens will keep up with the requirements of an immense colony in which most queens would fall far short. These presumably are of extra value; but their phenomenal laying exhausts them quickly, and they are not likely to last long.

BEES AND FRUIT-BLOOM FERTILIZATION.

Anent the articles of Thaddeus Smith, on pages 262 and 280, denying fruit-fertilization by bees—we can make believe we are Boers, and he can be a Britisher without making believe; and thus we will have a splendid chance to learn courtesy and fair conduct toward adversaries. He's right that pretty much all that class of experiments are *inconclusive* in which boughs or trees have been covered with fine netting. In thus preventing insect pollenization other modes of pollenization are also hindered, if not prevented altogether. Our folks must mend this defect and experiment some more. Apparently neither himself nor his friend are well posted in insect lore. We greatly need a skilled entomologist turned loose in May among the islands of Lake Erie. Quite possibly he would see with half an eye that the sheltered location keeps off predatory insects, and that nectar-loving insects are abnormally thick there. Moreover, from climatic and other causes, these islands are among the choicest spots on the globe for fruit-culture. The excellence of results without bees does not show all it seems to. Still, a chance for some competent and friendly hand to show how much better results can be attained *with* bees, and let us watch the present strawberry bloom, and see how many of us can "pink him" on his reckless assertion (page 280) that the blossoms of pistillate strawberries do not secrete nectar. Look for bees, of course, but especially look for *very small* insects.

HEALTH AND BED-CLOTHING.

On pages 248, 249, Prof. Cook has a splendid article on the health of the dear ones at home. I will not attempt to say over again his good precepts, but rather (as possibly

is too much my habit of late) "mouse" to see if I can't find a little heresy somewhere. He advocates plenty of bed-clothing—he's right—but then stands unmentioned the very prevalent evil of *too much* bed-clothing. Are we not getting somewhere near the bounds of heresy when we ignore such an evil—as if we should say, Folks ought to eat plenty of food, and not waste too much time about it? It's half in vain to have pure air outside the "kiver" if underneath, next to our persons, the air is thick with excreted gases and thin of oxygen. And that's the state of things which must exist with unnecessary sheets of cotton-battings over us. And is not the result a torpid skin—almost as bad as weak lungs? Or, am I wrong about this whole business?

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

Because You Keep in Tune.

There is a harmony that runs thro' all God's works of love,
It rises thro' the hum of earth to join the choirs above;
And if your heart desires a part, morning and eve and noon,
In the wide chorus, sing your best, and always keep in tune.

The voices close beside your ear may grate discordantly,
And sometimes all the world around seems to be out of key,
But hold the note you know is true, sing clear and sweet, and soon
Others will join the melody because you keep in tune.

—PRINCESS LEONARD.

SUCCEEDING BY READING.

I am sure we are all glad that Mr. Hutchinson, visited the Cogshall's, and gave us the beautiful pen-picture of their home. The remark of W. L. Cogshall to Mr. Hutchinson is so pregnant with sense and truth that I wish to take it as a text on this occasion. "The man who reads is the man who succeeds."

I have always remembered something I read of Beecher's years ago: "Show me a man's library, and tell me of the company he keeps, and I will tell you the man's character." It has often been remarked that we owe our civilization to the discovery of the printing-press. Sure it is that without the stored-up wisdom which we have in the blessed books that grace our homes, our progress would be very much less rapid. I think I said in a previous number of these "Home Circle" papers that I wished I was able to put the Youth's Companion into every home in our country.

I have also said that there were three things I would strive to develop in the child from the very first—as soon as he could lispen—"papa" or I could make him understand my wishes—"truthfulness, self-control, system." I wish to add now that I would also strive to interest the child in reading, good reading, from the very earliest moment. The little nursery magazine should be among the child's first possessions, as soon as it can enjoy pictures or tingle with pleasure at the story. This should be followed by Saint Nicholas and the Youth's Companion. Of course, the child can not read these at first, but how delightful it is for father and mother to sandwich in the Sunday walk between the talks and readings on Sunday, and surely a little time each week-day can not be better spent by either parent than by giving it to the children with some good book or paper as the third party. If we commence thus early, I think there will be rarely any difficulty in interesting any child of ordinary intelligence in the child book or paper. In case the child does show indifference, the parents should tax invention till they succeed.

I know of one little boy who was quite a trouble to his parents in his very early years by a discouraging indifference to book and paper. He would enjoy their reading to him but was very slow to read for himself. A visit to some little friends who possessed a menagerie of white mice, interested the boy greatly, and nothing would do but that he must have like pets. The parents, of course, were interested in his desire and suggested that he find out where he could buy them, what they would cost, and suitable cages or homes for the little rodents, when they should once be secured. The result was that the little fellow hunted the papers over for advertisements regarding white mice. The parents seeing

here an opportunity at once secured the papers, which treated of pet stock and were delighted to note that not merely the advertisements but everything about the prospective pets was not only scanned but thoroughly read. The pets came, were housed according to the latest rules and improvements, and were for a little a great pleasure. They soon, however, lost their attractiveness, but the taste for reading commenced in the scanning for advertisements, ever remained. These parents never see white mice but they feel grateful for their share in the development of a taste for reading which has ever been of inestimable value to their boy.

Mr. Coggeshall's implied reason for reading—that it brings success—is certainly one not to be neglected. We all remember "Seidan" and the speedy undoing of Louis Napoleon. I have seen it often stated that the greater intelligence of the German army explained the quick conclusion of that momentous conflict between the two great nations.

I have been greatly impressed as I have visited among our farmers, not only in Southern California, but also in the East, to note how the best success in the field and orchard always goes hand in hand with a good library and numerous excellent papers in the home. It is true that in the past, frugality, native sense, and a close attention to business, would often bring success even to the unlettered. But that day is becoming a thing of the past. Competition is rapidly crowding the weakling to the wall. This is becoming as true in agriculture as in other lines of business. Very soon the man that succeeds must know the best and practice it. He must be fully up to the times. To do this, he must possess the books and papers, and must be a close reader of the same. What has given such sections as Western New York, Northern Ohio, Michigan, all of New England, their supremacy in the way of progress and advancement? Unquestionably it came from the fact that they were preeminently a reading people. The home-table gave to the home circle the best of books and magazines, and such papers as The Country Gentleman, Rural New Yorker, and American Bee Journal took no second place among the literary works in these homes.

In speaking to our people of Southern California, I often hold up one hand with fingers and thumb extended and explain upon five things of which, we of this State, have great reason to be grateful: Our mountains, our wondrous climate, our incomparable fruit, our pure water right from the mountain rocks, and last and best of all, our splendid people. Visitors from the East often remark upon the splendid cultivation which they note in the orchards of our Southern California. They often say there is nothing to compare with it in the East. If they should look in upon the home circle of an evening, they would make the more interesting discovery that this intensive culture was not alone characteristic of the orchard work, but was equally true in the mind-field. I have heard it said that every one reads in our Southern California homes. While very likely this is an exaggeration, it certainly is true that ours is a reading community, and is destined to become entirely so. The man who does not read must catch the habit or move out. This is a kind of blessed heaven, and every community may well pray that it be brought in liberal gauge to their "home circles."

But the business advantage is by no means all that comes from this habit of reading. We not only need men who know the details of their work, but we also stand in pressing need of men with broad views, men who grasp the right relations of things, men who have broad sympathies, that go beyond neighborhood, State, or even country. With what pride and gratitude we have all noted and followed the course of Mr. Hay, our Secretary of State, as he has managed the intricate problems of our recent international affairs. We would not have been so honored if he had not been a man of widest view and broadest sympathy. In this case the whole world is to feel the influence and receive an uplift because of the wide-reaching stretch of a single mind. It goes without saying that Mr. Hay could not have taken the proud place which he occupies except for the fact that he was a man of widest reading. His culture stopped not with his home affairs, but he shows that he understands the temper and relations of the various other nations even better than they understand each other. It is, then, one of the best uses that we derive from wide reading, that our view is broadened and we are not disturbed by the petty things of life, but are able to grasp the right meaning of the great events, and so are able to plan and work for the greatest good of all.

Every right-minded person loves companionship. Even the dear Master, in those bitter hours in the garden, was sorrowful when the disciples fell asleep and could not watch with him in that terrible hour. I never see a good man or a good woman treading life's pathway alone that I do not feel sorrow-

ful, and wish that a better fortune had granted to them the dear companionship which is the brightest crown of the best home circle. Even the most favored of us can not always have our loved ones about us. Death, cruel circumstance, often forces separation whether we would or not. Then it is that the book comes as a very angel of mercy. Who of us has not driven loneliness from our homes and hearts at least by a short-lived forgetfulness as we have chosen for our companion the treasured words of some great author? That greatest and best-loved American—Abraham Lincoln—it is reported, had but two books in the long preparatory days of youth—the Bible and Shakespeare. Yet what good use he made of them. The one made him companion of many of the greatest minds and greatest hearts that ever blessed the world; yea, it did better than this, it gave him a heart that reached out even to the most lowly of God's people and was ever alive to the needs and sufferings of those about him. Except for reading, and these two great teachers, who were such good companions during the long, prosaic days of Lincoln's boyhood, we should have been poor indeed, for we should not have had Abraham Lincoln to put the superlative gilding upon the pages of our nation's history.

The ability to entertain one's self, and to be happy even though all our friends depart from us, is certainly one to be treasured among the best of our possessions. A library full of the masterpieces of literature, and a taste and desire to seek out the best they have for us, will do more than aught else in the world to drive ennui and the gloom of loneliness from the one whom bitter fortune has separated from the loved ones. It is a problem, and no less a puzzle, to many of us to know how to keep the children interested in the home, that they may not know of the evil or be enticed by the sinfulness that the street and even worse places are ever reaching out to lure the precious children into ways that lead to death.

I have two habits of mind for which I have never ceased to be grateful. I think I am mostly indebted to my mother for them. She was the mother of a large household, and the cares incident to her life, minding as she did not only the household, but butter and cheese making, and often the care of the yard, made her life, I think, one of the fullest that I ever knew. Mother loved books and nature. She was never so busy that she could not get a little time each day to read, and, as I look back, it seems to me one of her best pleasures was in reading with us children, or going out to interest us in some insect or flower that seemed peculiarly interesting and beautiful. The result of all this was not only to make mother the dearest companion of my childhood, but such a love of books and reading that I never find the time to drag heavily, or the days or hours to last too long.

I remember once, a few summers ago, I was dropped at Yucca, one of the most desert places of our great mid-continent desert. Numerous others were alike unfortunate. I think I never knew more yawning in a single day or more complaint against fortune. Yet it was one of the most interesting days that I ever spent. A book, describing the natural history of the country and the numerous object-lessons right at my feet which vividly illustrated the word-picture of the book, made the day all too short. It was with regret that I greeted the evening and the coming train that was to bear me away.

The greatest good from books, is the soul uplift, for this is immortal. Space permits me only to mention it here.

Please send us Names of Bee-Keepers who do not want get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

The Premiums offered this week are well worth working for. Look at them.

was in 1897. Since then, as every one knows who reads, California has had a series of dry years. That being the case, no industry has suffered worse than apiculture, and, to illustrate, I will cite a few of the losses that have come under my personal observation. I will begin with my own apiary: At the close of the season of 1957 I had 120 colonies of bees, but sold all but 45 of them. Since then I have bought 304 colonies, and at the beginning of this season I had 147 colonies. I have done far better than the average, and will give a short table, omitting names, and using letters instead. This will represent different apiaries in the five counties of Southern California that I know of—their conditions in 1897 and in 1961:

1897 Colonies.	1961 Colonies.
Mr. A. 110	20
Mr. B. 75	24
Mr. C. 150	60
Mr. D. 185	100
Mr. E. 25	65
Mr. F. 80	20
Mr. G. 25	1
Mr. H. 45	00
Mr. I. 65	00
Mr. J. 27	1000 (7 cols.)
Mr. K. 70	40
Mr. L. 200	100
Mr. M. 800	500
One district 5 miles across it 1500	240
Mr. N. 100	34

I could go on, but it is unnecessary. This is sufficient to show something of what the loss has been in Southern California; and that is not all, for the honey-producing plants have suffered also, many of them having died.

I think the majority of the bee-keepers who have any bees left will try to build up their apiaries, but increase in an apiary that is run for extracted honey will be at the expense of the honey crop.

Up to the present time we have had so much cloudy and cold weather that my bees have stored comparatively little honey, and if any one can, under the now existing conditions, see the prospect for a large honey crop in California for 1961, I vote him the palm.

Since writing the above I have received an offer of 4 cents per pound for 15 tons of nice sage honey. How does that strike you?

J. W. GEORGE

Riverside Co., Calif., May 1

Nectar Going to Waste in Michigan.

The bees are very busy on fruit-trees and dandelion. Bee-keeping is in its infancy in this locality. There are thousands of acres of raspberry, clover, willow-herb, basswood, goldenrod, asters and many other honey-plants too numerous to mention, that are wasting their nectar year after year.

I am 27 years old, and commenced bee-keeping at 17. I am very much interested in it. I have always been in the habit of carrying bee-papers in my pockets instead of tobacco. Whenever I found any one that I could interest I would either give him sample copies, or tell him the valuable information they contained, and I find I have been well paid for my trouble, as I have interested quite a good many in bee-keeping.

ELVA E. COVEY

Emmett Co., Mich., May 18

Transferring from Box-Hives to Movable Frames.

Some time ago some one gave instructions for transferring bees and combs from box-hives to movable frames. His instructions called for thorns run through the holes in the frames into the edges of the combs, thus pinning them fast. Now, I haven't the thorns at hand, and even if I had I have a way that I like better, and I think others will: I also have better success in getting the combs to stay in, and it makes them much straighter, too. My plan is as follows:

Wire the frames the same as for putting foundation in them. Then cut a piece of board a scant 3/4 inch thick that will just fit into the inside of the frames, and nail this to a board of convenient size, say 2 inches larger

ITALIAN BEES AND QUEENS

Having been 28 years rearing Queens for the trade on the best known plans, I will continue to rear the best.

M. H. HUNT & SON, Bell Branch, Wayne Co., Mich

each way, to be used for a lap-table. This can be used for putting in foundations as well as the old combs. Fit the pieces of old combs together as closely as possible, and trim all all around even with the smaller board, then lay the frame on top of the combs, holding it down steady and firm, and cut with the knife close along the wires down to the mid-rib or septum, pressing the wires down firmly in the crease. Lay another lap-board on top, and turn the whole thing over on the other side. Lift the first board mentioned and lay aside. Have some narrow wood splints made, say 1/4 inch wide and as long as the frames (wood separators make good ones), then tack on 1, 2, or 3, according to the sizes of the pieces of comb used, and the work is done except, of course, that the splints are to be pulled off after the bees have attached the combs to the frames.

I have many combs made up in this way which are as straight, and but for the line of connection between pieces of comb can not be told from one built upon foundation.

Consign all crooked pieces of worker-comb and all drone-comb to the extractor, as the profits from them will not pay for the "put-teration" necessary.

The bees have done good work on willow bloom, but rain and cold weather held them from fruit-trees entirely. Some of the fruit is not yet through blooming, and the dandelions are out, but the cold weather keeps the bees from them. F. W. HALL.

Stout Co., Iowa, May 13.

Lost 8 Colonies—Dandelion in Bloom.

I had 65 colonies of bees last fall, but have lost 8 of them up to date. Dandelion is in bloom, and fruit-trees will be in a few days if it gets warmer. It is quite cool and windy to-day, and rains a little. F. F. BAKER.

Allegheny Co., N. Y., May 13.

Bee-Sting Remedy.

I noticed in the Bee Journal an inquiry for a bee-sting remedy. I use iodine, and if applied at once there will be no swelling and the pain will cease in a few seconds. This remedy can be used even on the youngest child without injury. H. W. HAMILTON.

Walker Co., Ala., May 14.

Uniting Weak Colonies in Spring.

This is considered by many experienced bee-keepers love's labor lost. J. B. Hall, in the Canadian Bee Journal, has this to say:

This I have found from practical experience is waste of valuable time. It is all very well to do it as an amusement, but for profit never unite two or three, or ten weak colonies. See that they have enough honey, keep them shut down, and give them a good letting alone, and they will be sure to pull through. If you have ten, and you put after them, there is only one queen left, and that may be the poorest queen of the lot. You have not only lost four or five, but you have destroyed the good queens, and very likely have a poor one left, and you have nothing but your queen. Don't unite in the spring, let them pull through if they can; if they don't, you have the live for something better when the warmer season comes. That is my experience after 25 years. I used to unite them, and when we put them together they made a very good-looking colony of bees, both in honey and bees, but in three weeks from that I had only one colony of bees, and, therefore, I think my time was wasted. You know as well as I do, that those bees are old, and will live a few weeks only, and they don't pay for the labor of uniting them with a colony that has a queen. You may lose your queen by

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00.

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipt, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

that uniting, and if you do not lose that queen those bees are old, and are going to pass from the stage of action in a very short time.

Light-Weight Brood Foundation.

J. M. Rankin reports in *Gleanings in Bee-Culture* a series of interesting experiments which are a bit surprising in their results. He put in nine different hives comb foundation of different weights, the heaviest running 6 Langstroth sheets to the pound, then 7, 8, 9, up to 13 sheets to the pound, putting in the same hive foundation of two different weights for the purpose of comparison, giving an equal show to vertical and horizontal wiring.

He found it more difficult to put the thin foundation in the frames and wire it; but the bees showed a preference for the lighter foundation by working it first, their preference being strongly marked when the heaviest and lightest were put in the same hive. With vertical wiring, 10 sheets to the pound was the lightest that could be used without having the sheets wavy and stretched between the wires. With horizontal wiring all sheets, even those running 13 to the pound, made straight and even combs. Tons of foundation are now made in sheets running 9 and 10 to the pound, which weight was formerly considered entirely too light for brood-combs, but it now appears that by using horizontal wiring it may be used even as light as 13 to the pound, making quite a saving. The difficulty of satisfactorily wiring such light foundation, however, should make one a little cautious.

Foul Brood and Its Treatment.

In the Canadian Bee Journal for January, 1901, I see that Mr. Pender, editor of the Australasian Bee-keeper, advises the hiving of foul-broody bees on starters of comb foundation as a pretty sure way of curing the disease.

I judge Mr. Pender to be a good bee-keeper, and a man that would treat his colonies before they became bad with foul brood, and then doing his work so carefully and so well that he made a success of curing all by hiving the bees on starters of comb foundation.

The number of cures that can be made that way will depend entirely upon the following conditions:

1st. On how little diseased honey the bees find to take out of the old combs when they are being removed.

2d. Where much of the honey in a foul-broody colony is badly diseased, everything will depend upon whether anything is to be placed above the queen-excluder to catch the diseased honey after the bees are given the starters, if the starters are not to be removed.

In the honey season of 1875, while curing my own apiary of foul brood, I took all the combs out of several diseased colonies and left the bees to build combs on the bare frames, and in a short time I had about as many failures as I had cures. This method cured every colony that was not bad with the disease, but failed on every colony that had been bad with foul brood, and had a good deal of unsealed honey in the brood-nest when the old combs were removed. Just as soon as the bees had a little comb made they stored part of the old diseased honey in it, and a little later on foul brood made its appearance again. I then resorted to taking away all the new pieces of comb that the bees made during the first four days, and let them keep what they made after that. This plan thoroughly cleansed the bees of all the diseased honey, and ended in perfect cures. I also cured many colonies that summer by the use of clean combs and the frequent use of the honey-extractor, and in the fall of that year, after brood-rearing was all over, I cured quite a number of foul-broody colonies by shaking the bees onto sound sealed stores. This plan

left the bees no place to store the diseased honey, and forced them to keep it until they consumed it, and that ended the disease.

All of these plans and methods I studied out 25 years ago last summer and fall, when I had to treat 50 out of 60 colonies in my own apiary for foul brood.

When foul brood matter is drying down it glues itself fast to the lower side and bottom of the cells, and there it will remain as long as the comb lasts, and during honey-flows the bees store honey in many of these diseased cells, and after that foul brood is spread through a colony in proportion to the amount of honey that they get from the diseased cells to the sound larvae. In the honey season, when we are taking the combs out of the diseased colonies to cure them, the bees (finding the unsealed honey so handy with no unchipping to do) rush into the open cells and take all they can hold, and where many of the diseased cells are full of unsealed honey (as they usually are at such times) the bees will get pretty well filled up with diseased honey before all the combs are removed. To cleanse the bees of this honey I give them starters of comb foundation, and in four days the bees make them into little pieces of comb and store the diseased honey in them. I then (in the evening) remove all the combs that the bees made in the four days and give them full sheets of comb foundation, and before this is worked out the cure will be complete. This is the safest and most practical method for all classes of bee-keepers to follow, and one that never fails. It is one thing to cure an apiary of foul brood and quite another to do it and make more or less honey, and have all colonies in grand condition when the season closes, and this can be done.

When I am examining an apiary I mark each colony according to the condition I find it in. I put one pencil cross on the front of the hives that are strong in bees and have only a little of the disease; two crosses on those that have less bees and more disease; and three crosses on those that are weak in bees and badly diseased. In the evening, in the honey season, I pick out the weak colonies that have the three crosses on, and shake the bees of every three into an empty hive, so as to make good, big colonies to start with, and then give them the starters, which are to be removed in the evening of the fourth day, and full sheets of comb foundation put in their place. I take the hives next that have two crosses on, and put the bees of every two of these into an empty hive and treat them. I then remove the combs out of the hives that have one cross on and shake the bees right into the same hives, and treat them.

Where I find only a few cells of the disease in colonies that have large quantities of nice, clean brood, I save this brood with some bees on it and fill up two-story hives with it. I then set these hives back a little distance from the others, and when the most of this brood is hatched I go in the evening and shake the bees into a single hive and treat them and give them a queen.

The increase of colonies that I make by hatching out the bees from the brood during the honey season (which is the only safe time to do this) more than makes up for the old bees I have lost.

All curing and treating of diseased colonies should be done in the evening, so as not to have any swarming out and mixing in with other colonies or bees returning to the old stand after they have been mixed with others.

This same method of curing can be carried on at any time from May to October, when the bees are not gathering any honey, by feeding plenty of sugar syrup in the evenings to take the place of a honey-flow.

All the combs and pieces made in the four days should be made into wax. Wm. McEvoy, in the Canadian Bee Journal

3-Frame Nuclei For Sale

We have a few at \$3.00 each. Address, **GEORGE W. YORK & CO.**, 144 & 146 Erie Street, CHICAGO, ILL.

POULTRY BOOK FREE, 64 pages, illustrated with 3 mos. trial subscription to our paper, the **INDIAN POULTRY JOURNAL**, Indianapolis, Ind.

Standard Bred Queens.

100 Different Styles of Fence—It seems almost poor boasting that one little machine which can easily be handled and moved about by one man is capable of weaving over 100 styles and kinds of farm, lawn, poultry and ornamental fencing. This is, however, true of the Duplex Kilt Bearing Woven Wire Fence Machine. It is manufactured by our advertising patrons, the Kitselman Brothers, of Muncie, Ind. The cut shown with this article gives a very good idea of the machine and its method of operation. It also shows one style of farm fence in course of construction. The Duplex will handle satisfactorily any and all sizes of wire, using large wires for laterals and weaving on any number of smaller sizes of wires. It will also weave perfectly a fence with desirable barbed wire at top and bottom, and a style of fence much sought after and appreciated in certain localities. Fence may be made of any desired height up to 50 inches. As to capacity, this will vary somewhat, depending upon many things, but the manufacturers state it conservatively at from 40 to 60 rods of farm fence per day. The Standard Duplex Machine makes a fence up to 50 inches high as stated above, but at a small additional cost special machines may be had which will make fence 5 1/2 and 59 inches high, respectively. The Duplex is well and honestly made of good material, and with anything like ordinary care will last indefinitely. Kitselman Brothers are also large manufacturers of Ornamental Fence and Gates. These fences are made entirely of wire and in the greatest variety of form and fanciful designs. They are so constructed that they will turn all sorts of marauders and at the same time increase rather than detract from the beauty of the enclosure. The ornamental gates and the neat steel posts and rails greatly set off and increase the beauty and strength and value of the fence. Write these people requesting further matter on fence material, ornamental fencing and gates and all classes of fence materials, and don't forget to mention the American Bee Journal when writing to them.

ALBINO QUEENS If you want the most prolific Queens—If you want the gentlest bees—If you want the best honey-getters—ever saw—try my Albino, Untested Queens in April, \$1.00; Tested, \$1.50. 11A26 J. D. GIVENS, LISBON, TEX.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, May 26.—Market is nominal in almost all places; a little comb sells at 150c for choice white, with the amber grades ranging from 20c less. No movement at any place; no quantity in extracted, all dealers seeming to be expecting a lower range of prices. A little fancy white clover and basswood sells at 70-80c, depending on flavor, quality and quantity; taken; ambers, 60-70c; dark and buckwheat, 50-55c. Beeswax steady at 30c.

R. A. BURNETT & Co.

DETROIT, May 21.—Fancy white comb, 14 1/2 to 15; No. 1, 13 1/2 to 14; dark and amber, 10 1/2 to 12. Extracted, white, 6 1/2 to 7c; amber and dark, 5 1/2 to 6c. Beeswax, 27 to 28c.

Very little desirable honey in sight. The new crop will find the market well cleaned up. The demand is always light at this time of the year.

M. H. HUNT & SON.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from 1/2 to 1 cent per pound.

C. H. W. WEBER.

BOSTON, May 21.—Our market continues dull on honey with very light stocks. The best normal prices are as follows: Fancy 1-pound cartons, 17c; A No. 1, 16c; No. 1, 15c; No. 2, 12 1/2 to 14c. Extracted from 6 1/2 to 7 1/2c.

BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, 15c; white, 24-frame cases, per case, \$3.40; No. 1, 15c; amber, \$3.00. Extracted, 6c.

PRESTON BROS.

NEW YORK, May 3.—We report quiet market on all lines. While the old crop of comb honey is well exhausted, still there is some arriving, which has been carried by the producers, eventually, for a higher price. Values are mostly nominal now, and it is only a first-class fancy article that will sell at quotation prices. We quote: Fancy white, 15c; No. 1, 13c; amber, 10 1/2 to 12c; buckwheat, 9 1/2 to 10c. Extracted is decidedly dull, and very little inquiry. Old crop of California light amber and partly white, is now being offered as low as 4 1/2 a pound f.o.b. coast, which, of course, hurts the sale of other grades to a large extent. Beeswax is firm and sells on arrival at from 28 to 29c.

HILDRETH & SEGELKEN.

BUFFALO, May 18.—Fancy 1 lb. comb, 15 1/2 to 16c; dark very dull indeed, 8 to 12c. Berries hurt sale of honey now.

BATTERSON & Co.

KANSAS CITY, May 4.—Practically no shipments arriving, and very little selling. We are getting \$3.50 to \$3.75 per case of 24 sections No. 1 white; amber, \$3.00 to \$3.25. Beeswax scarce at 25c.

W. R. CROMWELL PRODUCE Co.

Successors to C. C. Clemens & Co.

ALBANY, N. Y., May 3.—Honey market very dull. Very little call for anything but choice comb honey, of which there is scarcity. Extracted quiet.

H. R. WRIGHT.

SAN FRANCISCO, May 15.—White comb 11 to 12 cents; amber, 8 1/2 to 10c; dark, 6 1/2 to 8c. Extracted, white, 5 1/2 to 6c; light amber 4 1/2 to 5c; amber, 3 1/2 to 4c. Beeswax, 26 to 28c.

No large quantities of new honey have yet put in an appearance, but the anticipation of heavy receipts at an early day is imparting a weak tone to the market. Free purchases are not possible, however, at current quotations, and dealers may find it necessary to pay higher prices than now nominally current before securing any considerable portion of this year's crop.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

When Lilacs Bloom.

When lilacs bloom, the winds grow still;
The velvet deepens on the hill;
The bee turns giddy as she greets
With long-drawn, happy kiss, the sweets
The lavish, low-flushed blossoms spill.

The daisy dons her whitest frill;
The oriole his gladsome trill
Sings loud, and oft his joy repeats,
When lilacs bloom.

Then lives with careless rapture fill;
Then hearts with joy of living thrill;
And Fancy weaves her golden cheats—
Ah! who would doubt the fair deceptions?
No room for reason, thought, or will,
When lilacs bloom.

—JESSE F. O'DONNELL.
In The Chautauquan.

MR. G. SPEARMAN, says the British Bee Journal, probably has the largest apiary in Great Britain, containing more than 300 colonies.

MR. A. P. RAYMOND, writing from Clark Co., Wis., had these kind words to say:

FRIEND YORK:—I am still reading the American Bee Journal, and am much pleased with the improvements you are making from time to time in its bright pages, and which make it more enjoyable, if such a thing be possible.

I sincerely appreciate the successful efforts you are making to keep it "up to date" and abreast of the times. A. P. RAYMOND.

PROF. A. J. COOK, the editor of the department of "The Home Circle" in this journal, is a man who has long been before the bee-keeping public. We think we can hardly do better than to copy what the "A B C of Bee-Culture" has to say concerning Prof. Cook and his work:

Albert J. Cook was born Aug. 30, 1842, at Owosso, Mich. Those who are intimately acquainted with the man will not be surprised to learn that his parents were thoroughly upright Christians. The daily reading of the Bible, with comments by the father, reinforced by the constant example of a chaste, honest, and industrious daily life, left its impress for life on the character of the son.

At the age of 15 he entered Michigan Agricultural College, where he graduated at 20, having been obliged during his course to suffer the sharp disappointment of suspending study a whole year on account of sickness, his health having been rather delicate during his earlier years. Upon his graduation he went, on account of poor health, to California, where for three years he labored very successfully as a teacher. He then studied a portion of two years at Harvard University and Harvard Medical College with Agassiz, Huxley, and Dr. O. W. Holmes as teachers. In 1866 he was appointed instructor at Michigan Agricultural College, and in 1868 Professor of Entomology and Zoology in the same college.

He has done and is doing a work unique in character, for he instructs the students, not only about insects in general, but about bees in particular. Every student that graduates goes all over the theory of bees, studies the bee structurally from tip of tongue to tip of sting, and goes through with all the manipulations of the apiary—that is, if there is any honey to manipulate; handles the bees, clips

queens, prepares and puts on sections, extracts, etc. Probably in no other institution in the country, if in the world, is this done.

Prof. Cook was an active and influential member of the North American Bee-Keepers' Association, of which he has been president; was one of the originators of the Michigan State Bee-Keepers' Association, of which he was president for a number of years, and helped to start the State Horticultural Society, being a member of its board for some years. He is widely known as a writer. His "Manual of the Apiary" has reached a sale of 18,000 copies, and "Injurious Insects of Michigan," 3000 copies. He is also the author of "Maple Sugar and the Sugar-Bush," of which 5000 copies have been published. He has written much for bee-journals, as also for the general press. He is a clear, practical writer, with a happy style.

In the battle waged against insect-foes, he has rendered valuable service. Remedies which he first advised are now common, and he was probably the first to demonstrate the efficacy and safety of Paris-green for codling-moth.

Prof. Cook is of average height and weight, a charming conversationalist, and an intensely interesting lecturer. His very pleasant manner is only a fair index of a genial and loving spirit that, in an unusual degree, strives to put the best construction on the conduct and motives of every one, and that, in the charity over their faults. His spirit of kindness extends to the brute creation; and on his farm, in which he is much interested, he has some fine-blooded stock; and in attempting to engage a hand to work upon the farm, the writer once heard him stipulate as essential that the employee must be kind to animals, and free from the use of liquor, tobacco, and profane language.

In December, 1893, Prof. Cook removed from Michigan and went to Claremont, Calif., where he now fills the chair of Entomology in Pomona College.

We can add hardly anything to the foregoing, except to say that we heartily endorse its every commendation of Prof. Cook. We are glad to count him among our friends. We believe that he is doing some of his very best work for bee-keepers in his department in this journal. His careful early training, and long years of experience with young people, both in and out of college, eminently fit him to advise wisely in everything that pertains to the home and its members. If what has already appeared from his pen in the new department is a prophecy of things to come, we may all expect many a rich feast during the future weeks and months. Our hope is that all who read his sage teachings may profit by them, and thus cause many a home and home life to be better and sweeter because of his efforts.

WORSE THAN WASTED.—The drink bill of this nation is, for the year, \$1,634,565,787, or \$13.94 for every man, woman, and child. I believe the drink evil is the worst problem that civilized countries have to contend with, and sooner or later all right-thinking men must line up, either for or against the saloon. So far as I am individually concerned, I propose to fight the saloon through any organized effort that will mitigate this terrible evil.—**EDITOR.**—Gleanings in Bee-Culture.

No one ever need apologize for being against the saloon. It's the other fellow that ought to be ashamed of himself. Chicago is one of the hotbeds of the saloon curse, and such havoc as it produces! The only reason it is here is because the good people don't stand together and cast it out. Some day they will unite, and then—good-by to the greatest vice, crime, and poverty breeder in the world. We believe every reader of the American Bee Journal is ready to join in the final overthrow.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., JUNE 6, 1901.

No. 23.

✱ Editorial. ✱

Renewing Queens.—Bee-keepers differ in opinion and practice as to the matter of renewing queens. Some say it is best to leave the matter entirely to the bees. In a state of nature they always renew their queens when they have attained an age of perhaps not more than three years, in rare cases allowing them to become four or five years old. Others say it is best to have only young and vigorous queens, never tolerating a queen more than two years old, while still others put the age limit lower yet. They say, "Breed only from your best, and never allow a queen to reach an age of two years, and your stock will be constantly improving."

All agree that it is right to breed from the best, but it is not always easy to tell which is best if an age of less than two years dooms a queen to death. A queen would hardly be replaced earlier than some time in June, and the harvest of that year would be largely the work of the progeny of her predecessor. So that leaves only the harvest of one year to judge from, and that is not so good as more, for accidental causes sometimes come in the way of deciding that would not occur a second year.

The matter of wintering is to be considered. There is no doubt a difference in colonies in this respect, and a queen whose bees should winter well for three or four winters in succession, other things being equal, should have the preference.

It is possible that longevity should be considered. It is well known that sometimes a colony exceeds the average in storing, while at the same time its queen has not reared as many young as the average, and some think this is because of a difference in longevity, a worker living a week longer than the average being able to store a fourth more than the average, for a bee is not expected to do more than four weeks of field-work, usually. It is also true that some queens live longer than others under the same conditions, some queens doing as good work in the third year as the first. It is not unreasonable to suppose that if a queen is longer-lived than the average that her workers will share in that characteristic. So it might be safer to breed from a queen that had done good work for three years, and such queens would not be known unless superseding were left to the bees.

Still another point in favor of leaving the matter of superseding to the bees is that it

interferes the least with the work of the bees. When a new queen is given by the bee-keeper, it *may* be so introduced that there will be very little interruption in the laying, but there will be almost certainly some degree of interruption, and it *may* be serious; whereas, in the case of superseding by the bees there need be, and generally is, no interruption, mother and daughter often laying for a time side by side.

Along with all this is the fact that it is a good deal easier for the bee-keeper to leave such matters to the bees, and so it is no great wonder that many of the most experienced say that superseding is a matter that rightfully belongs to the bees.

Scientific Breeding.—Arthur C. Miller, in *Gleanings in Bee-Culture*, broadly hints that editors of bee-papers and authors of bee-books are ignorant upon the subject of heredity and scientific breeding—a charge which he is probably pretty safe in making; but the reading of his article does not add much to the reader's stock of knowledge upon the subject. About the only paragraph that gives any instruction up the subject is the following:

"Thoroughbred" is not "crossbred," as any high-class stock-raiser will testify. Thorough breeding is cautious, careful, scientific in-breeding (do not confound this with in-and-in breeding); and when alien blood is introduced the result can never be foretold with certainty, the chances being toward *atavism*, the reverting to a previous type."

Even that does not explain the difference between in-breeding and in-and-in breeding—merely says they must not be confounded. The seeker after the difference who goes to the dictionary will not be helped much, for he will find one of the definitions of "in-bred" to be "bred in-and-in." But Mr. Miller's object is probably merely to call attention to the prevailing ignorance, and in that view of the case his article is timely. Never, probably, was attention so much drawn to breeding for improvement of stock, and Mr. Miller is quite right in saying, "It is high time we began to be scientific in our work. The haphazard, guess-at-it-rule-of-thumb ways have prevailed altogether too long."

Introducing Virgin Queens.—George W. Commins says in the *Australasian Bee-keeper*, "A virgin queen can be introduced if there are queen-cells in the hive, by just running her in." Editor Pender replies in a foot-note:

"Virgin queens can not be introduced with any certainty of success when more than an hour or two old. Any colony, having queen-

cells started several days, will receive a virgin queen that has just emerged, and often such queens will be accepted by bees if allowed to run into the hive immediately the laying queen is removed, but there is so much uncertainty the practice is not usually adopted. Try a virgin say 12 hours old and I think you will fail every time."

It may be remarked that on this side the globe there is good authority for saying that a virgin queen just from the cell (not one that has been held in the cell by the bees) will be kindly accepted in any colony, whether queen-cells are present or not, even in a colony with an active laying queen. That is meant in the broadest sense, that such a queen will not be disturbed in *any* colony whatever, and yet such a statement without any additional word would be very misleading. Put such a virgin in a hive with a laying queen, and although she may be received ever so kindly, you may find her missing a day or two later. It looks as if the bees did not recognize any royalty about her till she attains a few hours of age, after which she will not be tolerated. If, however, it is late in the season, when supersedes are likely to take place at the close of the harvest, then the bees may take the new-comer and allow her to dethrone the old queen.

Securing Control of a Territory is sometimes an easy matter, and sometimes not so easy. In making plans for extending by way of out-apiaries, Harry Lathrop says in the *Bee-keepers' Review* that his first step would be to secure a suitable location where he would lease a small piece of ground in a sheltered nook, and then says:

"Having secured the land for a term of years, I will erect a small, cheap building that will serve as a shop, extracting, and bunk room. A cellar will be dug, in sloping ground, of sufficient size to winter 150 colonies, which would be the maximum number that I would expect to keep in that yard. I would fence and clean up the ground and make it as neat and handy as I could at a small expense. Then I would buy up all the bees that were for sale on the field, and begin to form my apiary. . . . One can usually buy at a fair price what few bees the farmers have on such a field."

Perhaps, and yet in many cases the very fact that farmers knew a man was engaged in establishing an apiary of considerable size would arouse in them the thought that more was in bee-keeping in that locality than had supposed, resulting in an immediate rise in price. Indeed, it has very frequently been the case that the establishment of a prosperous apiary has induced others to go into the business to a considerable extent who never thought of such a thing until they saw the establishment of that prosperous apiary.

Convention Proceedings.

Report of the Minnesota Bee-Keepers' Convention.

BY DR. L. D. LEONARD.

The Minnesota State Bee-Keepers' Association held a convention Dec. 5, 1900, at Minneapolis. The meeting was called to order by H. G. Acklin, the chairman of the executive committee, the president, J. P. West, being ill; and, therefore, unable to be present.

After preliminary exercises, Vice-President G. H. Pond took the chair. The first business of importance was the report from a special committee consisting of Wm. Russell, H. G. Acklin and J. P. West, on the adulteration of honey. This committee had collected samples of honey from different parts of the State, and took them to the Dairy and Food Commissioner for analysis. It is due to this society, through the efforts of this committee, that the Dairy and Food Commissioner have taken a more active interest in the suppression of the adulteration of honey during the last year, than they ever did before.

QUES.—Is it well to extract all the honey from the brood-frames at the end of the white honey season?

Mr. Turnbull would not extract from brood-frames at all; Mr. Shepherd said the same; Mr. Perry would take part of the honey out; Mr. Russell thought that in small hives one should not extract from the brood-frames; and Mr. Acklin believes in extracting from the brood-frames, and that sugar syrup is better for the bees to winter on than honey.

AFTERNOON SESSION.

This session was held jointly with the Horticultural Society which was holding a convention in Minneapolis at the same time. Dr. L. D. Leonard reviewed the literature relating to the mutual relations of bees and horticulture, and the following paper written by Pres. West, on the same subject, was read by Mrs. Acklin:

BEE-KEEPING AND HORTICULTURE.

There are a great many things which are of interest to the bee-keeper and horticulturist, and if I were present I think I could say some things which would interest you, all applicable to both occupations; but to write them is another thing.

I take for granted that every up-to-date horticulturist believes that bees are great agents in fertilizing flowers that are not capable of self-pollination, and that they are a great benefit where cross-fertilization is a benefit and is desired.

Honey, as a general thing, is secreted only in such flowers as are incapable of self-fertilization; while those capable of being fertilized through the agency of the wind secrete no nectar to entice the bees. As examples, we see wheat, oats, barley and herds-grass, all capable of being fertilized by the rustle of their stalks by the wind. All the clovers and buck-wheat must be fertilized by insects. The poet puts it thus:

"Bees kissing the flowers: they sip its sweet,
But make the buds more fruitful and better to eat."

Prof. Bailey, of Cornell University, a very eminent horticulturist, says bees are much more efficient agents in pollination than wind, in our fruits, and their absence is always deleterious.

Mr. Morton B. Waite, of the Division of Vegetable Pathology of the Department of Agriculture, says many varieties of apples require cross-pollination, and the pollen must be from different varieties; and further he says (and from decisive experiments), plant mixed orchards, or at least avoid planting solid blocks of one variety, and be sure there are sufficient bees in the neighborhood to visit the blossoms properly.

Mr. A. C. Berry, horticulturist commissioner of Tulare County, Calif., has had great experience in this matter and has an orchard of several hundred acres. He says that bees and fruit go together; that he can not raise fruit without bees; and that he has them all about his orchard.

A Mr. McIntyre, in a horticultural meeting in California, relates his experience in starting an orchard, which was very large. It was started 35 miles from any bees, so far as he knew; when his trees were old enough, they blossomed but he did not receive any fruit. As the trees did not bear fruit he

was advised by other fruit-men and horticulturists to get bees, which he did, and his orchard bore profusely, and he said he had bees all around his orchard. Where there is a large area of orchard, clover, or blossoms of any kind, which require insects to fertilize them, Nature has not supplied a sufficient number of insects to perform the work, hence the necessity of keeping bees. I have about four acres of strawberries. In the season of 1899 and 1900 when they were in bloom they were very fragrant, and as the weather was very favorable for visits from bees and insects, they were literally covered with bees, and my berries were never so perfectly fertilized. Generally there are not many bees to be seen on the vines.

My market and money-making berries are the Warfield fertilized with the Bederwood. I have the plants in rows four feet apart and about two feet in the rows. I mow the vines after the season is over, stir up the mulch and burn when there is a good, brisk wind. Last fall, one year ago, I put 48 big loads of ry-o-straw on my beds; the straw made me \$300. That is, I cleaned up that after paying for picking at one and one-half cents. The crop was about one quarter of a crop, and without a heavy mulch I would not have had anything. It was so dry. We had no spring rain, and none whatever until I was about through picking. I never saw such a sight of blossoms, and never saw so much fruit set on vines as there was on this bed. If the good Lord had given me the usual rain in the spring I would have had an immense crop.

My land is a black, sandy loam, with clay subsoil, and with good rains in April I can raise a fine crop of berries. The Warfield set so many berries that but few matured, not more than one quarter as many as the Bederwood. I have tried, on a small scale, a great many kinds of berries, but never any that will make me the money as the two named. My customers, as well as myself, prefer the Warfield, and it is a wonderfully profitable berry on my land; but the Bederwood, in such a season as this, is more so. It produced berries every day, week after week, when everything else was drying up, and it looked for awhile as if the Millerites were going to have things their way, sure.

There has always been a great mystery in almost every apiary, why one colony of bees should gather so much honey in a season, when one right by its side, in apparently as good condition, and having the same management, will produce only about one-half as much honey. The learned editor of the *Gleanings in Bee Culture*, Mr. Ernest Root, thinks he has discovered the reason, and I am inclined to think that he is on the right track. Time will tell. To-wit, the difference in the length of bees' tongues. In measuring many tongues he finds there is a great difference in the length. In measuring the tongues from Dr. Miller's two best queens—those that produced the largest quantity of honey per colony—one measured 8-100 and the other 19-100; this is much better than the average. A Kentucky man sent some bees, and their tongues measured 20-100 and 21-100, and one measured 22-100. It takes long tongues to reach honey in red clover blossoms, and in many other flowers. If it should prove that Mr. Root is right, the man who has a queen that will produce bees with tongues 23-100 long, or longer, uniformly, has a Klondike right at home.

Perhaps Prof. Lutzer, of the State experiment farm, would help the bee-keepers of Minnesota by measuring the tongues of bees sent him for that purpose. This matter will be thoroughly tested next season, and probably decided, and if there is anything in it I would like to see some Minnesota bee-keeper win the prize.

I am often asked, Does bee-keeping pay? Mr. N. C. Alford, of Colorado, says it paid him. He kept bees for eight years and cleared \$61,000, after paying for all the bees and supplies and for labor hired. He generally had 250 colonies. He also owned 1000 acres of land and 500 head of cattle. The alfalfa fields of Colorado furnish an immense amount of bee-pasture, and Mr. Alford is not the only enterprising man who has made big money in keeping bees in Colorado. Twenty-four maiden ladies arrived at Denver on one train recently to engage in apiculture in that State.

In some localities in other States, during the past season, bee-keepers met with great loss by having their bees poisoned by those who sprayed the blossoms on apple and plum trees when in bloom. This matter was thoroughly discussed, and it seems from letters received from the experiment stations in Missouri, Indiana, New York and Ohio, that such trees should not be sprayed when in bloom. Laws have been passed in some States to prevent the spraying of trees when in bloom, and bees are visiting them. Spraying just before and just after bloom seems to be sufficient. This is a matter that should be understood by the horticulturist, and apiarist, par

ticularly in those sections where there are large quantities of fruit raised, and bees are kept. The interests of both the apiarist and horticulturist are the same, and both are necessary that the most good should come to each: they go hand in hand, and are the most interesting and ennobling occupations that man or woman can follow on God's green earth.

J. P. WEST.

This subject was discussed by the horticulturists, and considerable ignorance was shown by them in regard to it. The bee-keepers then adjourned to their own room, where the question-box was again opened.

QUESTION-BOX.

QUES.—Will cross bees gather more honey than gentle ones? Those in attendance were about equally divided on this question.

QUES.—What time in the spring is the best to put out the bees? Answer.—The first warm day after the snow has gone.

QUES.—Is the mammoth clover a good honey-plant? Answer.—The second crop will often yield honey.

QUES.—Would it pay the average bee-keeper to strive to rear long-tongued bees? Answer.—No.

QUES.—Is there foul brood in Minnesota at present? No member knew of any.

Transferring Bees From Box-Hives—Pollenizing Fruit.

BY G. M. DOOLITTLE.

A CORRESPONDENT says he has purchased several colonies of bees in box-hives, and wishes Doolittle to tell through the columns of the American Bee Journal the best method of transferring them to frame hives. The majority of our most practical bee-keepers of the present day believe that what is known as the "Heddon plan" of transferring is the best, taking all things into consideration, so far given. This plan is as follows:

Drive the bees from the box-hive and run them into a hive furnished with frames of wired foundation, the furnished hive to be placed on the stand the colony had occupied up to the time of transferring, while the box-hive with its combs of brood and honey, with the few adhering bees, is to be placed close beside the new hive. In 21 days after, when all of the brood shall have emerged into worker-bees, drive the bees again from the box-hive, driving clean this time, and, after destroying the queen with this last drive, or the one in the colony driven before, according to which is the more valuable, unite the bees with those first driven out, thus getting the bees all on nice, straight combs, and in good shape to give a good yield of surplus honey.

The combs are now taken out of the box-hive, the honey extracted from them, and they are rendered into wax to help in making more comb foundation.

Now, while the above is the best known plan where the combs in the box-hives are crooked or poor, and the season of the year that when the bees are securing honey from the field, yet if the combs in the box-hive are good, straight ones of the worker-size of cell, or we do not have the foundation, or we wish to do this work early in the season, before the bees have much brood or are getting honey from the fields, so that they will not draw out the foundation readily, then, decidedly, the old plan or method given in nearly all the standard works on bee-culture is the proper one to use. I never could understand the logic that melted up good, straight worker-combs, made the wax from them into foundation, wired the frames to keep that foundation from sagging, and then "transferred" the foundation into those wired frames, with an amount of labor nearly equal to that required to transfer the original combs, all for the fun of saying we had used a plan of transferring different from that of Quinby's and Langstroth's day.

Straight worker-comb, properly transferred into a frame, after being fastened by the bees, makes just as good a frame of comb as is the one finished from foundation; and a frame properly filled with comb, without any wires in it, is just as good for all practical purposes, as is the one

having wire in it, while the wire is a positive nuisance, if, from any reason, holes get in the combs from moldy pollen, mice or anything of the kind, so that we wish to put in a "patch" of worker-comb to keep the bees from building in drone-comb. I do not wish to be considered cranky, but when a thing savors of more money out than profits in, I have always felt it a duty, as well as a privilege, to enter a mild protest, after which I am not to blame if any see fit to use anything recommended which may result in a financial loss.

BEEES AND FRUIT-POLLENIZATION.

I have read twice the article by Thaddeus Smith, found on pages 279 and 280, and the second reading only emphasized the impression of the first, which is, that while he says, "I am set for the defense of facts," he seems entirely to ignore them or else is wholly ignorant of many things along the lines of which he is writing, that have transpired during the past. I will take space to speak of only two or three.

He wholly ignores those experiments made by Gregory, of Massachusetts, the great squash-grower, wherein he proved *positively* that not a single squash could be raised where insects were excluded from the female blossoms of that plant. And yet all Mr. Gregory did was to place netting which would have admitted millions of those "infinitesimal particles of pollen" which Mr. Smith tells us are the ones which float in the air and do the work of fertilization without the aid of insects or bees, if they are only stirred up with a stick, or by a breeze created by the bees' wings, in which case bees and insects may help a little.

Then he ignores the Wenham episode, which, through jealousy, excluded all the bees from that township, during which exclusion fruit was nearly or entirely absent in the interior of the township, while on its borders, to which the bees had access, fruit of usual quality or quantity obtained, the same as of yore.

And he can not have forgotten the importation of our bumble-bees into the continent of Australia, at a cost of thousands of dollars, after which importation clover seed obtained in fair quantities, when none perfected before. And with these facts within easy reach of his understanding he asks, "Who knows it to be a fact?" and says such claim "is all conjecture based upon preconceived theory." I believe that Mr. Gregory and history are as unimpeachable witnesses as any which *Pelée Island* can produce.

I do not care to notice Mr. Smith's trying to "hold me up to ridicule," for any intelligent reader would know from the drift of my article in the March 14 American Bee Journal, that only nectar-loving insects were intended, where I said "insects of all kinds." Trying to hold another up to ridicule does not count anything in an argument.

Swarms Selecting a Location—Historical.

BY A. P. RAYMOND.

A KNOTTY problem has been discussed in the American Bee Journal, regarding the time when swarms select their future home, whether before or after emerging from the parent colony. There are many questions pertaining to bees that, at the present day, we can answer with absolute certainty. There are more, perhaps, that we have been guessing at for many, many years, and are still as far at sea regarding them as were our grandfathers, 100 years ago.

The above question is one of those "stickers" that I think will never be solved until some bee has been educated to talk, and tells us all about it. After reading "Rip Van Winkle's" ideas on this subject, I thought I would consult John M. Weeks, whose work, published in 1836, I have in my library, and I found that he was probably about as near the truth regarding this matter as we are to-day, after a lapse of some 64 years.

Prof. Cook thinks (page 530 1900) that their future tenement is selected by the bees before swarming, but after issuing; they first cluster and wait until the queen is sufficiently rested before proceeding thither. How about second swarms, which are accompanied by virgin queens, that are as able and ready to fly as far as the most nimble worker-bee that ever spread a wing?

Rip Van Winkle, (page 777 1900), thinks that they wait until after clustering before making a move toward making a domicile. How about those occasional swarms that leave for the woods before clustering?

Let us give it up and admit that we do not know a thing about it.

By the way, speaking of John M. Weeks, few living apiarists know that such a bee-keeper and author ever existed; and yet I think he should be accorded a place in history alongside of Father Langstroth and Moses Quinby. He began keeping bees about the year 1800 in Salisbury, Vermont, and struggled along with log-gums and straw-skeps with varying success until somewhere about the beginning of the thirties, when he invented and patented a hive which was, in the matter of convenience, far in advance of anything before in use.

In 1836 he published a treatise on bees and their management—a very practical work, which, I suppose, was not very widely distributed, for two reasons: First, meagre transportation and advertising facilities; and second, the work was unpopular, because the author did not accept any of the superstitious theories so prevalent at that period, but gave them solid facts, which, even to-day, relating to bees, seem stranger than fiction.

There were no railroads in Vermont at that time, and it was 13 years afterward before the State could boast of one, in fact it had been only six or eight years since the locomotive made its first appearance on this continent, consequently the mail service was also very poor at this time.

According to Mr. Langstroth's biography in the "A B C of Bee-Culture," this work appeared two years before he (Mr. Langstroth) became the owner of his first colonies. I almost wonder that Mr. Langstroth, who was scouring the world for bee-literature about this time, never ran across this work. As a proof that he did not, I will quote from his work, page 244:

"My attention has been recently called to an article in the Ohio Cultivator for 1846, page 185, by Micajah T. Johnson, in which, after detailing some experiments, he says:

"One thing is certain, if bees, from any cause, should lose their queen, and not have the means in their power of rearing another, the miller and the moth-worms soon take possession. I believe no colony is destroyed by worms while an efficient queen remains in it."

"This seems to be the earliest published notice of this important fact by any American observer."

Now hear what Mr. Weeks says, 13 years before this, on page 51:

"Large colonies, that never swarm, are never destroyed by the moth unless they lose their queens, mill down, or meet with some casualty out of the ordinary course of managing them. The colony of bees are so numerous that their combs are all kept well covered during the moth season, so that no miller can enter and deposit her eggs."

Quoting from Mr. Langstroth's biography in "A B C of Bee-Culture":

"Mr. Langstroth at that time (1818) had never seen or heard of a book on bee-culture; but before the second year of his bee-keeping, he did meet with one, the author of which doubted the existence of a queen."

Now, Mr. Weeks not only admitted the existence of a queen, but he reared them, and had a method of his own of introducing them into queenless colonies.

Mr. Quinby in his work mentions T. B. Miner as being the author of a work on bee-culture which appeared probably a very short time before his own. Without a doubt, Mr. Weeks' work is the earliest treatise on bee-culture ever published in America, and I am convinced by his knowledge of bees, and the methods he employed in their management, that they were acquired only after years of untiring perseverance and hard study.

He seems to have done all in his power to advance and promote the interests of bee-culture—the art he loved so well; but the people were not as ready to accept the true facts as we are to-day, consequently his labor was, to a large extent, in vain; everything pertaining to bee-management at that early day being attributed to luck, and the almost universal answer to the query, "Why, don't you keep bees?" was, "I have tried them but they don't do well for me." No amount of reasoning could induce them to make another trial.

Considering all the obstacles that lay in his way, and the difficulties he had to overcome, I think that Mr. Weeks made a good fight, and he should not be entirely forgotten. Peace to his ashes, and all honor to the memory of John M. Weeks.

Clark Co., Wis.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

Out-Apiaries—Their Management for the Prevention of Swarming.

BY F. GREINER.

IT does not lie within the scope of this article to advise nor to discuss ways and means to bring our colonies up to the required standard of strength. It is supposed that at least the majority of our colonies have already attained that state of development.

The principal drawback in running out-apiaries is that the bees are apt to swarm, and that the swarms are apt to go to the woods. It is therefore imperative that our management be such as to prevent all swarming.

We might run our out-yards for extracted honey, giving plenty of room to both queen and bees, always supplying empty comb, etc.; there would then be no swarming. However, we wish to produce comb honey, principally, as we can find a more ready sale for it. Giving plenty of room alone does not have the desired effect, and we must adopt a different management. It would be of great advantage to have only young queens in our colonies—we would then not be troubled with swarms out of their season, which appear frequently, when colonies supersede their queens. All swarms that would appear during the regular swarming period we try to head off. We seldom have any indication of swarming in this locality sooner than June 15. Nearing this date we watch a few of the best colonies, and when we find them constructing queen-cells our operations must soon begin. Hives and supers must of course have been gotten in readiness before this time.

About June 20—some years not till June 25—I go to the colonies most likely to cast swarms. First I give a little smoke at the entrance, then rap on the hive. I aim to give the bees time to fill themselves with honey. The hive is now opened; it may be set to one side first and an empty hive put in its place. This latter should contain but six Langstroth frames or their equivalent, supplied with starters only. This super is placed on top over an excluder, which, however, may be taken out after a week's time. The danger of a queen entering the super is generally past after that time, and the excluder may be needed on some other hive, and may be removed.

After the bees have all filled themselves they are not apt to offer any resistance, and, without using much smoke, I now shake all the bees from their combs in front of the empty hive. I have "an eye out" for the queen and note her condition. After she has gone in with the majority of the bees, I place an entrance-guard over the entrance. Sometimes these shaken-off swarms leave their hive after the apiarist has left, and then the bees leave for other quarters. The entrance-guard is to prevent such an occurrence; it should be removed when making the next visit. The apiary is gone over in this fashion, always selecting the strongest colonies first to be manipulated as stated. A visit is made each week. If honey is coming in, even but moderately, the section-cases on these treated colonies will fill up surprisingly, especially if we have filled the sections with comb foundation, and, unless the season continues through a very extended space of time, there will be no trouble with such as to their swarming that season.

If buckwheat is a source to be relied upon, each of these colonies should receive four frames of comb or foundation at the beginning of the buckwheat flow, which will end the manipulations of the brood-chamber of the shaken-off bees.

The question now arises: What shall we do with the brood-combs we gain from week to week by our shaking-off method? I utilize them in two different ways, viz: For increase and for the purpose of getting extracted honey. At the beginning of the season I set apart a number of good colonies to take care of these brood-combs. They need not be the very best colonies, and still they must be populous enough to be able to take care of a full set of combs full of brood, for they are to receive, each in its turn, such a full story of brood as we gain it by shaking off colony after colony. I have said before that I always select the most prosperous colonies first for shaking off, so each successive week we have some colonies to treat in this fashion—have some brood-combs to dispose of. Our nursing colonies, which had received a set of combs full of brood one week, may receive another after a week's time, and a third after another week. Even a powerful colony given this brood from week to week, will not think of swarming—they are kept too busy taking care of the young. They become very populous and also store much

honey as the brood hatches, which may be extracted after all brood has hatched.

Should we have full sets of combs full of white honey, and we have more colonies to shake off, I practice giving a set of these heavy combs instead of a hive full of empty frames. I never have a young swarm on empty combs—not in my locality. I give either empty frames with starters or solid honey-combs. The honey in the latter will always go up into the sections as soon as the room is needed for breeding; but of course the honey must be of good color or it will spoil the looks of the nice white clover or basswood honey the bees may be storing in the sections at the time.

Some bee-keepers advocate and practice having young swarms—and shaken-off colonies—come under the same heading—on frames of foundation. Aside from getting perfect combs I can see no advantage in this practice. Foundation in the sections pays well, however.

In case I want any increase in the out-apiary I take the colony that has two or three extra brood-chambers and move it to a new location; the two uppermost brood-chambers, neither one containing brood young enough for queen-rearing, I place back on the same stand, giving queen or queen-cell in a protector. Of course we must be sure that the queen is in the part moved. If we have placed an excluder on, a week previous, we can be very positive where the queen is. The queen must always go to the new location. Extracting combs are given to the divided colonies as well as to all colonies not working in sections.

If it should seem desirable to reinforce any of the shaken-off colonies, a hive full of brood, after it has stood over an excluder for two weeks, answers the purpose well; I take it, bees and all, and place it over an escape on top of the colony to be re-inforced.—American Bee-Keeper.

The Dzierzon Theory of Parthenogenesis— Digestion.

BY PROF. A. J. COOK.

IT has always pained me to read anything reflecting upon one of the greatest discoveries ever made in natural history, that of Dr. Dzierzon, of Germany. The thoughtful bee-keeper may wonder at this remark. He says we may all note that virgin queens lay eggs and that these prove fertile. Yet they always produce male bees and none other. Old queens also frequently become wholly drone-layers. Laying workers are exclusively drone-producers. Surely, if we think carefully upon all these facts we would not wonder that the theory of parthenogenesis in regard to the production of drone-bees might be suggested to so thoughtful a bee-keeper as was the great German priest. Strange others had not made the discovery before Dzierzon did. Yet we would have supposed the circulation of the blood would have been easier of discovery. Yet it was not made until 1616. And this discovery by Harvey is considered one of the greatest ever made.

It is also easy for us to prove the correctness of the Dzierzon theory. Every extensive and observant bee-keeper has had oftentimes in his apiary queens that have failed to mate. He has noted that these queens would lay eggs, and he has also been disgusted to note that the entire progeny were drones. Whenever we read, then, that some apiarist of an experimental turn of mind has removed the eggs from drone-cells into worker-cells, and vice versa, and in so doing has changed the sex, we have a perfect right to put a large interrogation point after all his statements. Like the matter of mating in confinement, we may well write, "Interesting if true," but undoubtedly not true. Dzierzon's theory is a very great one, and all praise is due the great German bee-keeper.

As the readers of the bee-papers know, the Dzierzon theory has recently been called in question over and over again by no less authority than F. Dickel, of Darmstadt. He was editor of the Nordlinger Bienenzeitung. He holds that his experiments prove that normally all eggs were fecundated. He claims to have transferred eggs from drone to worker cells, and that these latter developed into workers. The reverse he also claims to have found true. It will be remembered that von Siebold and Leuckart proved by microscopic examinations that Dzierzon was right in his conclusion. Dickel contends that the dicta of these great scientists is no longer to be accepted. He says truly that the sperm-cell or spermatozoa would not be seen except at a very early stage in the development of the egg, and that very likely these observers made their investigation so late

that they would not have noted the sperm-cell although it may have been there at an earlier period. This is true as Dickel states, yet it is also a fact that in case of fecundation the spermatozoa are succeeded by the sperm nucleus and a starlike body known as the sperm aster. These are obnoxious, and their presence makes certain that a sperm-cell was previously in the egg.

Recently A. Weismann, under the title, "Über die Parthenogenese der Bienen," in Anat. Anzeiger, gives the results of three years' investigations. Weismann urges that there is no ground to doubt that von Siebold saw seminal filaments (even two to four in a single egg). Blochman, by sectioning eggs with the microtome, has seen the same, and these results have been confirmed later by Petrunkevitch. These, however, von Siebold could only have seen in the freshest eggs, which were all taken from worker-cells. The 27 drone-eggs which von Siebold studied, were all above twelve hours old, and so the failure to find the sperm-cells in these was not proof that they might not have been there at an earlier period.

The material that Weismann used in his experiments was principally obtained from Dickel himself. The eggs were taken from the cells, put at once into a preservative fluid, and sent to Weismann. Weismann finds that whether the eggs are fecundated or not can only be determined with certainty when it is killed at the time of the second maturation spindle. In the stage of the first maturation spindle, the nucleus of the sperm-cells is either without radiations, or else the sperm filament has not been transformed into a sperm nucleus. In either case there is great doubt if the sperm-cell can be recognized with certainty. In the second spindle stage, however, the radiations of the sperm aster are complete, and there is no danger of either overlooking or misinterpreting them. Petrunkevitch sectioned one hundred and twenty-three eggs, which were in the first spindle stage. Twenty-nine of these were worker-eggs, and twenty-three showed the sperm nucleus with evident radiation. On the other hand, not a single sperm aster was found in any of the ninety-four eggs from drone-cells. The result from the study of sections of eggs taken in the second spindle stage was still more conclusive. Of the sixty-two eggs taken from worker-cells, there was no mistake regarding the presence of the sperm aster. Two hundred and seventy-two eggs were taken from drone-cells and only one of these contained the significant radiation. As every bee-keeper knows, occasionally a worker-bee comes forth from a drone-cell. As I show in my "Bee-Keepers' Guide," the queen adds or withholds the sperm-cell at will. She may occasionally make a mistake. As I show in my book, she often does when she first commences to lay, as we frequently find at such times, drones scattered through the worker-brood. That, as Weismann suggests, she should occasionally make a mistake in depositing drone-eggs is no marvel. In the case where Weismann found the sperm aster in the egg from a drone-cell, no doubt the queen made such a mistake when she laid the eggs. Weismann, after making these elaborate experiments, concludes that Dzierzon's views are fully confirmed—normal eggs laid in drone-cells are not fecundated, and that those laid in worker-cells are always fecundated.

Dickel makes the observation that as soon as the queen lays eggs, workers enter the cell and busy themselves in some kind of manipulation. He thinks that they add saliva. In case he is correct in this observation, his conclusion that this has something to do with determining sex does not follow. Dickel further adds that if the eggs are covered at once after being laid, so that the bees can not visit them, they will not hatch even though left where the warmth of the hive would seem to make the conditions favorable. It has been suggested that in this case the eggs are coated with saliva and thus the escape of moisture is prevented which would otherwise prevent their hatching. I think there is some doubt about this, but in any event the determination of sex is in no way dependent upon these early visits of the bees. If the eggs are fecundated, either queens or workers will result; if not, we may as surely expect drones. The determination of the queen or workers is unquestionably dependent upon the quantity and quality of the food furnished them.

Dickel urges that there is a difference between drones produced by laying workers and those produced by queens, and he believes that the former are functionally imperfect. I have never believed that we knew that this was true. Weismann says that he sees no proof that it is so. There is, however, a slight though constant difference in the development of the eggs from the two different sources. This being true, it would not be surprising if we should find that

drones from laying workers were unable to furnish sperm-cells that would fecundate the eggs. That the drones from the two sources may differ would not be exceptional, as there is a wasp which has two kinds of drones. It is not known, however, whether or not these drones have a different parentage.

ARTIFICIAL PARTHENOGENESIS.

The interesting experiments of Morgan and Loeb, which show that by the addition of certain salts the unfertilized eggs of sea-urchins may be made to develop more or less completely, have attracted very general attention among naturalists. Recently, some further experiments by Pieri and Winkler have been made in somewhat the same direction. These scientists took the sperm, shook the same up in either sea or distilled water then filtered it and added the filtered portion to unfertilized eggs. As a check, other unfertilized eggs were placed beside the former and treated the same way except the decoction from the sperm was withheld. Many of the eggs to which the sperm extract had been added, partially developed, which was true of none of the others. It was found that the sperm extract made in sea-water was more efficient than that made in the distilled water. To anyone who has studied marine organisms, this is no surprise. These experiments are interesting to bee-keepers. It would seem that in certain cases other stimuli than sperm-cells may induce the commencement at least of development. How it is that the drone-eggs develop without any stimulus at all is still a mystery which possibly may never be solved.

WHAT IS DIGESTION?

I am surprised at what the Editor states in the opening paragraph on page 195. He says that Mr. Root is still in doubt about my criticism of his definition of digestion. I doubt if Mr. Cowan claims to be a physiologist. He quotes in giving his definition of digestion. He certainly quoted from a very able physiologist. I am sure, however, that this physiologist and no other would defend the definition. In all our physiologies we find a chapter set apart for the discussion of the subject of digestion. This chapter confines itself to the explanation of how food is fitted to be absorbed, and nothing further. In vertebrate animals, the digestion is done partly in the stomach and completed in the intestines. In the stomach the gastric juice is the agent of this digestion, and the proteids, like the albumen of egg, etc., are the food elements that are transformed. These are changed into peptone—a substance which differs from all other albuminoids in being very osmotic. Other nitrogenous substances will not dialize, that is, they will not pass through organic membranes.

Digestion is to change substances so that they may pass through and escape from the stomach into the blood. In the intestines, starch, sugar, and the fats, and possibly proteids not digested in the stomach, are digested. The agent in this work is the pancreatic juice. It has three distinct substances, one of which digests the starch, one the fats, and the other, proteids. This, then, is digestion.

Assimilation is quite a different thing. Another term for this is anabolism or constructive metabolism. This work goes on everywhere in the body. It is the changing of the nutritive elements into tissue and is the direct work of the cells which are found in all the tissues of the body. Where anabolism is very active, there the cells are very numerous, as seen in brain and muscle. Where the constructive metabolism is less active, there the cells are less abundant, as noted in bone and cartilage.

Surely, if Mr. Root will consult any physiology, or inquire of any of our leading physiologists, he will no longer remain in doubt regarding the correct definition of digestion. True, our dictionaries do speak of assimilation, as though it might be akin to digestion. Physiologists do not use it in this sense. Los Angeles Co., Calif.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

The Premiums offered this week are well worth working for. Look at them.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Drones Reared from Laying-Worker Eggs.

In examining my bees this spring I found one queen had died during the winter, and a laying worker was busy. Will the drones produced from that laying worker be a fit specimen for a queen to mate with? NEW JERSEY.

ANSWER.—Instead of one laying worker there were probably many. As the eggs that produce drones are always unfertilized, I know no reason why the unfertilized eggs of a laying worker might not produce fully developed drones. Yet I should rather not depend upon drones reared in such an abnormal way.

Workers With Drone-Eyes.

I send you a sample of bees that have heads like drones. These bees are just from the cells. The queen is one year old that produced them. They have heads like drones, as you will see. Just about one-third of the working force are like these. One head is all right, like others. This is something I never saw before. TEXAS.

ANSWER.—The case is one beyond my knowledge—workers with eyes like those of drones. Are you getting up a new breed of bees with increased powers of vision?

Prevention of Swarming—Other Questions.

1. We wish to increase our apiary to 200 colonies this season, and thereafter we desire to prevent a further increase. Will you give us the most practical method of the prevention of increase? We wish to know a method that has succeeded. We use the 10-frame Simplicity hive. Would it be practical to allow the swarm to come out and hive it in the usual way in a "hiving-box" on the old stand, take the parent hive away under a tent, cut out all queen-cells, take it back to the old stand, shake out the swarm in front of the hive, and then give them plenty of super room and ventilation?

2. Our hybrids seem to be inclined to swarm more than our pure Italians. Is this their inclination generally?

3. We would ask your approval or disapproval of a ventilator bottom-board as follows: Cut a hole through the bottom-board about the center 8x10 inches. Over this hole tack wire-cloth, and underneath the board place a slide made of wood that will close the hole or open it at will. This slide may be drawn to any extent as the heat of the hive may demand. Would such a device retard or discourage swarming? We have just constructed one such bottom-board and placed it under a populous colony. We find that, when the slide is drawn, the number of fanning bees is diminished. Our hives are on individual stands about 12 inches from the ground. We regard this bottom-board as a perfect remedy in a case of robbing. The hive-entrance may then be closed completely, and the slide drawn to give the bees plenty of air. The colony that is doing the robbing may be served in like manner. This will stop the robbing at once.

4. Which are the better honey-gatherers, the bybrids or the pure leather-colored 3-banded Italians from imported mothers? NORTH CAROLINA.

ANSWERS.—1. The probability is that the bees with your plan would immediately start queen-cells and swarm again. You will have better success to remove the old queen and cut out all queen-cells but one. As you wish to know a method that has succeeded, you might try this: Just before queen-cells are started, lift the old hive off the stand and put in its place a hive with foundation or starters; find the queen and put her in this empty hive; put an excluder over, and then set the old hive with its contents over the excluder.

2. Perhaps so; but there is not much difference.
3. Anything that allows entrance for more fresh air is a help toward prevention of swarming, but the same end would be more easily and more fully attained by raising the hive on four blocks.

4. Some of the hybrids will be better, and some not so good. The pure stock will be more uniform and more permanent in character. The pure stock is better to breed from, and will not run out so easily as the hybrids.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

TALKING BEES 400 B. C.

One would say that every intelligent bee-man, ancient as well as modern, knew that it took honey to rear drones, as well as more of it to feed them after they were reared. The two different sizes of comb-cells in the hive are too conspicuous to be ignored except by pronounced dullards—and it's easy to conclude drones too big to be reared in worker-cells. I would say then that perhaps it's not quite *certain* that Socrates knew of apiculturists who habitually practiced reducing drones by cutting out drone-comb. It may have been not much more than a dream of his active mind, that if he kept bees he would save honey by cutting out what drone-comb could be got at. Drone-comb is not usually in the heart of a normal colony. All the same, it's interesting to hear a man talk bee-manipulation correctly four centuries before Christ. Page 254.

MORE ANENT THE SCORE-CARD.

Mr. Greiner, on page 262, laudably tries to fix things so judges of bees at fairs can not ignore the drones. He hardly "gets there." Drones will still be mostly ignored, except under the fourth item. Suppose we change:

Color and markings of workers and drones..... 25
Size of workers and drones..... 30

and make it:

Color, markings and size of workers (10-10-10)..... 30
Color, markings and size of drones (5-5-5)..... 15

KEEPING YOUNG QUEENS CONTINUALLY.

The reform chariot of keeping young queens continually in every hive runs against quite a "hedge," against two hedges, in fact, when Doolittle and J. B. Hall both emphatically denounce it. But if you do remove old queens for that purpose, be sure and destroy all cells capped at five days. Page 263.

HIVING SWARMS A LA GEHRING.

And so Teacher Gehring would have his class hive bees by placing swarm and limb carefully in front of the entrance, as close as possible, and then blissfully watch results. I would respectfully put in a pretty strong protest. No doubt that succeeds nicely oftentimes; but, if I am right, a large percentage of swarms will refuse to move in as they ought—will just remain in a provoking-to-patience pile partly on the front of the hive and partly on the limb. What's the use to follow a method that fails half the time, when it's just as easy to succeed all the time? I don't say you can always succeed in making them stay, but you can practically always succeed in making them run in. The full details would be rather long for this department. With a big pot-spoon dose the hive—small doses and often. After awhile increase the dose, and anon fall to shaking instead of spooning. But keep most of the bees on the limb until they are running in lively. Most important of all, keep poking the entrance clear as often as it threatens to get blocked up. Waiting for stationary bees to start up is mostly a humbug. Make 'em "git furdur" right straight along. To some extent, and with due moderation, the smoker can be used to hustle them; but too much of it makes them fly badly. A brush of green twigs, to whip them and sweep them and stroke their backs, is better. And always smoke a cluster of bees gently (just what you can without making them fly) before you do anything with them. Just about as bad practice to manipulate swarms without smoke as it would be to open hives without smoke. Both can often be done; but what's the sense of it? Our

smoker dog doesn't charge anything for barking, and why should we bark ourselves—or go barkless, with three thousand thistles thrust through our bark? Took me about half my bee-keeping life to get this much of horse-sense through my noodle.

GIVING CELLAR-BEES A FLIGHT.

Whether it is profitable or unprofitable to give cellar-bees a winter flight is an important question. It is regarded by some, it would seem, as one of the unsolved questions. My impression is that the heavy old chaps are mostly in the negative. May be I count 'em wrong. F. W. Hall's experience, page 268, seems quite decidedly in the affirmative—and with this quite healthy Irish bull I'll rest a bit from my afterthinking.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

SOUL-GROWTH FROM READING.

There was one advantage—the greatest one—which comes from reading that space crowded out of our last "chat" in "The Home Circle." I refer to the moral uplift—the soul-growth. We all agree that valuable as is bodily vigor, and desirable as is mental growth and power, both pale before spiritual development and influence. The outcome of Samson's colossal muscle was to pull down: Shakespeare's incomparable mental grasp which so enriches our literature and quickens thought, did not lift the whole world to a higher plane. Christ's life, which touched the spiritual that is in man, raised the whole world to better thought and purpose. It is the transcendent glory of any soul to be able to lift spiritually a brother soul. It is the most blessed gift that any of us can receive, to gain inspiration towards a more Christ-like life. The reading of good books is the mightiest force in moral development and spiritual uplift. May I speak of our own college?

We have about 200 students. A majority of these (61 gentlemen and 42 ladies) are engaged in voluntary Bible study. Many of these not only meet with one of their number, selected for special fitness as leader, for an hour each week, but all study the lesson for a half-hour each day, many taking the time just before breakfast. I believe that there is no one thing that promises more for the real success of our College than does this fact—nothing that so surely bespeaks a useful future for our students.

To spend an hour each day in close mental touch with Elijah, with Paul, with Christ, gives an equipment for life that is beyond estimation. The inspiration that comes from reading good books secures to the world such nobility of soul as was in Lincoln: such purity, sweetness, and such wealth of vital, moving spiritual force, as came to us in Longfellow and Whitier.

Soul-culture is the richest adornment that any person can possess. Soul-culture makes a great people, a worthy nationality. Soul-culture alone can rightly solve the China and Philippine problems. The reading and study of good books will be the greatest force to bring to us this priceless soul-culture. Mr. Cogswell, none of us can overestimate the value that ever comes from the reading and study of our best literature. Whatever we do, let us not neglect the matter of reading in the home circle.

BOOK AND MAGAZINE CLUBS.

It is good to have several of our best books, magazines, and papers—more than many of us can afford to subscribe for. May I tell how we manage this? I like the daily paper, which usually takes about ten minutes of my attention each noon-time. I cut the price in two by taking it with my next neighbor. Do all in our home circles know how much they lose by not joining in friendly co-operation with the good neighbors? We all have the very best neighbors in the world. Many of us do not know it because we do not know them.

To digress: Three of my neighbors and I own a row together. Such friendly partnerships make a pleasant neighborhood atmosphere, and I believe brighter home-circles. Eight of us neighbors each take a magazine. Thus, we have the Century, Atlantic, Scribner, Popular Science Monthly,

Harper's, The Forum, North American Review, and an art magazine. These are passed each week, and each one has his magazine to keep in the end. I take and keep one magazine. I have the reading, or opportunity to read, eight of our best magazines. I feel rich in this arrangement, and I am glad to suggest that many of our home circles enrich themselves in some such way.

Our book club is another of our neighborhood co-operative institutions, which is now several years of age. This has a still larger range. Eighteen of our Claremont "home circles" profit by this admirable arrangement. We all wish to see, possibly to read, surely "to thumb over," all the best books of the year. We each pay \$1.50. This secures 18 books. We all unite in securing the volumes, and as we are all alert during the year, we are likely to make a good selection. We rarely secure a book that we regret later to have purchased. There are one or two such each year. We each keep a book two weeks, and must date the day we receive it. Each day that a book is kept beyond the specified time requires a fine of 5 cents. At the close of the circuit the books are sold to the members by auction, and always bring in more than half cost.

I recommend this, or some kindred plan, to all our home circles. It is very popular, and deservedly so, with us. I presume I read about one-fourth of the books, and "thumb over" all of them. Cook reads many more, and daughter Bertha some more than do I. Thus we get as a family quite an insight into the best that is written in America and England each year.

Anything that incites those in our American home circles to read more and more thoughtfully the best books and papers, should receive the fostering care of all of us. May not our bee-keepers profit by something like our magazine plan? There is always something in each of the bee-papers that is valuable to each of us. There are articles in each, and some number of each, that some of us do not care for at the time. To have them all would be a signal gain. In almost every neighborhood there are not five bee-keepers that get mail at a single post-office? In such case, five magazines or journals could be taken, and by a convenient exchange all have all. If such an arrangement could be generally carried out, can any one doubt but that it would be a substantial gain to our industry? When any one reads, and so handles his business more wisely, all are gainers. The slovenly, unlettered bee-keeper slumps the market with his inferior product. The up-to-date, thoroughly-read bee-keeper advances the market, as all first-class products are sure to raise prices.

THE FARM FOR CHILDREN.

Mr. Coggeshall keeps his farm at a loss because Mrs. Coggeshall wishes it for the children. God be thanked for such wise mothers as Mrs. Coggeshall. Such mothers will not have to grieve over wayward children as the years roll on. A distinguished writer, and college president, says in one of the last month's magazines, that our cities would soon die of rot were it not for the fresh blood from the country that pours annually into them. Strange that the city business man does not recognize that his virility comes from the vigor of body, mind, and integrity, which was bred in the country home of either his or his father's boyhood. If he recognized this he would take time to come and go. Mrs. Coggeshall would say time given that our "best crop," the boys and girls, should be a truly "best crop," is time best employed.

The country home builds industry, purity, truthfulness, righteousness, into character. The country home is the very saviour of our country. The rush from country to city is full of menace. May we not hope that a better judgment may swing the tide, and that we shall soon see a flood, at least for the boyhood of our people, from city to country? I wish Mrs. Coggeshall's words could be sounded into the ears of every parent our country over.

COMMITTING SCRIPTURES TO MEMORY.

My fortunate boyhood's home circle was richer, better, for hearing the Bible read each morning. I would not have had that part of my early culture omitted for a fortune of what the world calls riches. I, to-day, can hear the words and comments of my dear father, though he has been dead for years. These memories are a priceless legacy. I could not deny my children what had been so precious to me. So I have always read daily from the "Book of books." I have often wondered if my words read, and my comments, would be such a benison to my children as were my father's to me. Some parts of the dear old Book are so incomparably precious that we have learned them. Thus we have the Ten Commandments, many verses from Isaiah, the 1st, 2d, 8th, 19th, 23d, 24th, 121st, and 17th Psalms, the Beatitudes, Romans 12th, and 1st Corinthians 13th, etc. We often, instead of reading, repeat. It is blessed to know these chapters by heart. It is blessed frequently to repeat them in concert in the home circle, after the morning or evening meal.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us 100 or 150 W. subscribers to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.00.

GEORGE W. YORK & CO.

St., Chicago, Ill.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

Farm Wagon Economy.

The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., who make this Electric Handy Wagon and the now famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

**ELECTRIC**

This wagon is composed of the best material throughout—white hickory axles, steel wheels, steel bounds, etc. Guaranteed to carry 400 lbs. These Electric Wheel Wagon are made to fit any wagon, and make practically a new wagon out of the old one. They can be had in any height desired and any width of tire up to 8 inches. With an extra set of these wheels a farmer can interchange them with his regular wheels and have a high or low-down wagon at will.

Write for catalog of the full "Electric Line" to Electric Wheel Co., Box 16, Quincy, Ill.

Please mention Bee Journal when writing.

The Rural Californian

Tells all about Bees in California. The yields and Price of Honey, the Pasturage and Nectar-Producing Plants; the Bee-Ranches and how they are conducted. In fact the entire field is fully covered by an expert bee-man. Besides this paper also tells you all about California Agriculture and Horticulture. \$1.00 per year; 6 months, 50 cents. Sample copies, 10 cents.

THE RURAL CALIFORNIAN,

218 North Main Street, - LOS ANGELES, CAL.
Please mention Bee Journal when writing.

The American Poultry Journal

325 Dearborn Street, CHICAGO, ILL.

A Journal that is over a quarter of a century old and is still growing must possess intrinsic merit of its own, and its field must be a valuable one. Such is the

American Poultry Journal.

50 cents a Year. Mention the Bee Journal.

BARNES' FOOT POWER MACHINERY

Read what J. I. PARENT, of Charlton, N. Y., says: "We cut with the use of your Combined Machines, last winter, 50 chaff hives with 7-in. cap, 100 honey racks, 500 brood-frames, 2,000 honey boxes, and a great deal of other work. This winter we have double the amount of bee-hives, etc., to make, and we expect to do it with this Saw. It will do all you say it will." Catalog and price-list free.

THE MODERN FARMER & BUSY BEE.

EMERSON TAYLOR ABBOTT, Editor.

A live, up-to-date Farm Journal with a General Farm Department, Dairy, Horticulture, Livestock, Poultry, Bees, Veterinary, Home and General News. Edited by one who has had practical experience in every department of farm work. To introduce the paper to new readers, it will be sent for a short time to New Subscribers, one year for 25 cents. Sample copies free. Best Advertising Medium in the Central West. Address,

MODERN FARMER,

9Ctf ST. JOSEPH, MO.

Please mention Bee Journal when writing

GENERAL ITEMS**A Report from Massachusetts.**

This is more of a market-gardening country than anything else, with dairying as a side-issue. There is no buckwheat raised to speak of, and very little white clover. About 50 colonies, I should judge, are kept within a radius of two miles from here. Are "kept," I say, but most of them keep themselves. They are in box-hives owned by people who never saw a bee-paper, and would not look at one if they could, because their fathers never did. In extra-good years they sometimes get a little surplus honey, but in poor years their bees starve. I bought one colony in a box-hive for \$2.50 last spring (hybrids, I should think), from which I took 29 pounds of fine-comb honey. The combs were very white and well filled out, but the honey was rather dark, almost of a greenish color, but very thick. I do not know what it could have been gathered from. The bees did not swarm last year, but will probably do so this year, and I hope they will do still better. They have wintered well on the summer stands.

Mrs. E. C. FOX.

Middlesex Co., Mass., April 10.

Prospect for a Successful Season.

We have 34 colonies, and the season bids fair to be a successful one. Many of our hives are already so full of bees that they are hanging outside considerably. None have swarmed as yet.

I find the American Bee Journal very useful.

Pierce Co., Wash., May 11. S. M. ALLEN.

Clover and Bees Wintered Well.

Bees wintered well, and the prospects for a honey crop are good. Clover was not winter-killed as it was the two previous winters.

W. J. BROWN.

Ontario, Canada, May 12.

Prospect for a Good Honey Crop.

Colonies of bees are getting very strong if it is cold, and the prospect is good for a large honey crop.

Winnetka Co., Ill., May 24.

Migratory Bee-Keeping—Moving Bees.

I have done more or less migratory bee-keeping for a number of years, and have hauled bees over all kinds of roads, in all kinds of weather, and in every style of life. The hive matters but little, except that if it is large and cumbersome it will make a difference in the number that can be hauled at one time. I have only one large horse, and a wagon made expressly for hauling bees, heavy but with very easy springs, thus causing very little jar, and never breaking down combs, although I have carried some very frail ones.

In the clover season my bees are taken to my "Tucker" apiary, and at the close of this flow I take them to the Zack Chandler marsh, where there are thousands of acres of Spanish needle, which grades with clover in this market.

In preparing the bees for removal I have only the bottom-boards fast. Nothing else is done to them except to remove the covers if the hives will not tier up easily with them on. I use no wire-cloth, and never close the bees in. I drive to the yard, unhitch the horse, and about dusk begin to load up. I usually select a moonlight night, thus combining pleasure with business. I have never had an accident in moving them in this way, for if they find themselves at liberty and therefore settle down contented, while if they are shut in

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00.

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat feather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—first come, first served—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

they will worry and gnaw, and if there is a possible chance they will rush out and cause trouble. I remove them regardless of strength; some of the hives may be full of bees, but there will be no danger of trouble.

The most important thing to be considered in moving bees is which way the combs shall be placed—toward the horse or crosswise. Many of the readers will remember our good old friend and bee-master, J. H. Townley, who in the early '80's gave me, as well as many others, our first lessons in bee-keeping, and who advocated placing the combs lengthwise. But after years of practical experience on all kinds of roads, hilly, stony, up-and-down, trotting the horses, etc., I find that combs placed crosswise are more safely carried. There are more or less ruts, sticks, stones, etc., on any road, while up or down hill one always walks a horse or team.

Ingham Co., Mich.

A. D. D. WOOD.

Prospects Good.

Bees are doing well. Clover is plentiful. Prospects in general are good.

D. J. BLOCHER.

Stephenson Co., Ill., May 16.

Bees Working on Dandelion Bloom.

Our bees have been doing very well the past two weeks on dandelion and other bloom, some of the colonies having 50 pounds or more of surplus honey in the extracting-combs. A northeast wind and rain prevails at this time, which is interrupting their work; but if the storm does not end in a killing frost there will no doubt be an abundant flow of raspberry and other honey as soon as the weather is warm enough.

H. W. CORNELISON.

Washburn Co., Wis., May 23.

A North Carolina Report.

We have an apiary situated in eastern North Carolina, which is being run for comb honey. Last year the spring opened with 75 colonies in very poor condition, owing to the fall bloom being cut off by storm the August before. Last year was one of the finest honey-years ever known here, and our 75 weak colonies built up and gave us 5,000 pound sections of honey. About three-fourths of this was white honey.

We wintered our bees last winter in single-wall hives on the summer stands without the loss of a single colony, except that two were found queenless. This brought us out this spring with 122 colonies with queens. Nearly all of these were in good condition. April was a cold, wet month, and the bees pulled through under difficulties.

The apiary is situated in a pine thicket bordering on a farm. The trees are 50 or 60 feet high, hence we have to clip our queens that we may be able to control the swarms. We have had 24 swarms up to date.

Occasionally a queen will emerge, with her wings, which is the result of superseding. One such came out to-day and lit in the top of a pine 50 feet high. We were anxious to bring her down, fearing other swarms might join her. We tried jarring the tree with an ax, thinking that she would get tired of flying and alight lower; but she resisted our efforts until we desisted of being able to capture her alive. When she became an "outlaw," five shots from a Winchester repeating shotgun brought her to the ground, together with many of her followers.

BASTER & FARNELL.

Pamlico Co., N. C., May 18.

A Colorado Lady's Experience.

I bought 16 colonies of bees and united to 13, a year ago last fall. This was too large a start, according to all the advice I could get, but I wanted to go in that depth. I spent about \$100 on bees, new hives, etc., and last year I spent \$100 on all sorts of supplies. The bees have yielded honey enough to pay for themselves and the cost of keeping them. I now have 23 colonies in fine condition, so I think.

I have read so many bee papers and books that I am just bursting with information, but

when confronted by a live bee, or a practical situation. I feel very ignorant and helpless. I had such a queer experience in introducing queens last year. There was no pasteboard over the cage-hole. One colony had been long queenless, though I had just found it out, and the other had an imperfect queen. I didn't know that, either. Some time before, I knew their queen was dead, and gave them a frame of eggs, which were too old, I think. Well, the queens came at night, and I was too impatient to wait till morning, so opened the hives and placed the cages between the frames. I waited a week and then looked in to discover that neither queen had been released! I waited three days longer, and found that the bees having the drone-layer had killed her and accepted the new queen. I found out then for the first time that they had a drone-layer.

Looking in the other hive I found the queen still imprisoned, and so I let her out myself. Two weeks later both hives were full of young brood—an astonishing quantity! Neither colony was worth requeening, apparently, but I wanted to try an experiment. Then I was very anxious for fear the brood would chill and the queens wouldn't go through the winter, for I saw they were weak. I fed both colonies, and covered them up snug and left them. Now they are running over with bees.

Imprisonment didn't seem to injure those queens. I am afraid I will lose track of them when they swarm. I have never tried clipping, but do not fancy it.

(MISS) JOSEPHINE FIELD.

Las Animas Co., Colo., May 12.

The Uses of Honey.

Mr. Herman Cook, of Wyoming Co., Pa., sends us the following, taken from the New York Tribune, contributed by J. F., of Preston, Conn.:

The ancients regarded honey as a celestial food, and they used it at all religious ceremonies. The Egyptians used it as a remedy for various diseases. The Jews, from the Bible, honey was for the Hebrews as indispensable as milk and flour, and it served them as an excellent medicine for the gout, coughing, and all kinds of wounds. For the Arabian, honey is of great importance, as is shown in the Koran by the story of the man who one day came to ask Mahomet what to do for his brother who was suffering great pain, and about to die. The prophet prescribed honey, and the man followed his advice. After a short time, however, the man returned and told Mahomet that the remedy, instead of alleviating the evil, only made it worse. But the prophet answered, "Go home and continue to give honey to your brother, for God speaks the truth, and your brother's body has lied." And the patient recovered after a continued use of the remedy.

The ancient Greeks used honey as a means to prolong life. Pythagoras lived only on honey in order to keep healthy his body as well as his mind. Other examples are those of Democritus, who died at the age of 90, and Ameron, who died at the age of 115. Both were very fond of honey, and consumed it in large quantities.

Therapeutically, honey is much employed in diseases of the mouth. It is known that these diseases (thrushes) very soon disappear after the application of honey in combination with alum or borax. When children are teething their gums are rubbed with a decoction of marsh-mallows (the root of Athene officialis), or saffron with honey. For pains in the throat gargling with honey and lemon juice is an excellent remedy. As curatives are further known the Oxyne scillaria vinegar and honey, and the saffron wine, chevlil, kangawed, white wine and honey. Also the application of diluted honey to burns, chilblains in this case the honey is combined

"THE GARDEN BOOK."

A NEW BOOK ON GARDENING.

BY T. GREINER.

This is a new book on gardening. Mr. Greiner has for 30 years been preaching and practicing the gospel of good gardening with marked success, and hence is well qualified for the task. Thirty years of actual soil-contact by a man who loves his work and follows it in all its details with indelible patience, means much when it comes to teaching others. In the "Garden Book" the author epitomizes that 30 years' work in a most entertaining and instructive manner.

The man who has a garden, large or small, and the man who intends to have one, will be greatly interested and profited by a study of its pages. It is one of those books which inspire its readers to reach out for better results through more thorough work, and is in line with the previous writings of Mr. Greiner, which have done much to advance the gardening interests of the United States. The book is handsomely printed in clear type on fine paper, containing 120 practical illustrations. It is right for every-day reading, and right for every-day reference.

Price, postpaid, 50 cents; or with a year's subscription to the American Bee Journal, both for \$1.00. We will mail it free as a premium for sending us ONE NEW SUBSCRIBER to the Bee Journal for a year with \$1.00.

GEORGE W. YORK & CO.

143 & 145 Erie Street, CHICAGO, ILL.

Ten Days on Trial.—In the past several years certain manufacturers and others, with that knowledge and unbounded faith borne of experience, have offered various sorts of things to the farmer to be first tried by him and paid for only after he is convinced of their merit and satisfied with the bargain. So far as we know, however, the Kalamazoo Carriage and Harness Co., of Kalamazoo, Mich., is the first firm in the United States offering to send out carriages, buggies, wagons, harness, etc., on this plan. Those of our readers who have followed their advertising as it appeared from time to time in our paper, will have observed the proposition. The plan is to send articles which appear in their catalog to anybody, anywhere, on 10 days free trial. The purchaser orders the vehicle he may wish, and when it is shipped, he goes to the railroad station, hitches up to it and drives home. He can use it in any legitimate way and subject it to any testing from reasonable use for the space of 10 days. If at the end of that time he is satisfied with the job, he simply pays the catalog price for it. If not, he ships it back to the factory.

This appeals to us as being about as fair and open a method of doing business as it is possible to adopt. It is certainly a most gracious compliance to the honest and fair-minded farmer of our country. It gives them the opportunity to see and try just what they are buying, and to test it in every way before being obliged to pay for it. Certainly the manufacturers, who will offer their goods to people on such liberal terms, have unbounded confidence in the value of their wares. We should expect, under these conditions, that the Kalamazoo Carriage and Harness Co. made only first-class vehicles, and trimmed and finished them only in a first-class and enduring manner. Any of our readers who are in need of a vehicle or harness of any kind should write them at once for illustrated and descriptive catalog. They mail it free. Please mention the American Bee Journal when writing.

with oil of turpentine, inflammations, and in many cases of veterinary practice, are almost generally known.

To preserve the complexion there is nothing better than honey-tail which, a hundred years ago, were much in use among the ladies of the stage, and have to-day again come in vogue in Paris.

Spring Feeding in the Fall.

The Canadian Bee Journal reports that very practical bee-keeper, J. B. Hall, as saying:

"As far as spring feeding is concerned I am a lazy man, and I have found it is better to give the spring feed in the month of September than in the month of May. I have advocated in the past, never open your colonies until the fruit blossoms, unless there is something wrong with them. If you want to know their strength, and can not tell by the noise they make, tip up the hive and look underneath—to do break the quills. This may make the difference of a crop of honey. You open them in the spring to see if they are queenless—what good can you do them if they are queenless? Let them be."

Money Not the Highest Success.

W. A. H. Gilstrap enters some good sense in the Bee-Keepers' Review when he says:

"Many make more than a living at home, mainly from bees, who could make more money to scatter their time and business all over the country, and still have less of life's real success than at present."

"To illustrate, you can find places, isolated perhaps, where you can make more money with a system of out-apiaries than you are doing at present; but you would necessarily have to be away from home more, would be worth less to your family, to society and yourself, than in your present capacity. To make the suggested change would be very unwise."

In-Breeding.

The opinion is commonly held that without occasional introduction of fresh blood one's stock will run out, and that continued in-breeding means final decay. Under usual circumstances the opinion is probably correct, but it should be known at the same time that in-breeding under skillful and intelligent management may produce very desirable results. The editor of *Gleanings in Bee-Culture* says:

"Very recently my attention has been called to a series of articles in the *Jersey Bulletin* on the subject of in-breeding to get prize-winning stock. I was surprised to note how the breeders of high-class Jersey blood in-bred. In one or two instances I noticed that a mother had been bred to her son, and sisters to brothers, for the express purpose of accentuating certain desirable traits. I observed, further, that this practice has been carried on to great advantage for many years. Bee-keepers have much to learn from the breeders of other fine stock. But inbreeding is one difficulty to contend with, and that is, that of getting a particular queen mated to a particular strain of drones."

In the same paper J. H. Gerbracht says:

"I think I will say a word right here about in-breeding. There is not in existence to-day a single strain of unusual superiority of either cattle, hogs, or chickens, in which this principle has not been employed to secure a fixed type; and after this has been done, the fixed type can be maintained only by the most careful and scientific line-breeding. Crosses between different strains produce just the same unreliability and tendency to degeneration as crosses of distinct breeds do, except in the few cases in which, either by accident or the exercise of most unusual good judgment, the two strains happen to 'click' well. In cattle and swine breeding, the infusion of one-eighths new blood is considered enough to offset whatever ill effects close in-breeding may

produce, the idea being to use the least possible amount to maintain the vigor and stamina with as little disturbance of characteristics and type as possible; and the success of the breeder depends to a great extent on his ability to do this accurately.

In poultry-breeding, particularly in the varieties which have variegated plumage, in-breeding and line-breeding are the only ways by which any fixity of type can be secured; and some breeders boast of not having gone outside of their own yards for breeding-stock for 30 years. Of course, the results are sometimes the same as those attained by some breeders of five-banded bees—good to look at, but of no utilitarian value; but this is by no means necessarily the case; and the best laying and most vigorous stock we have to-day is from this same line-breeding."

Assaulting the Bees.

A writer in *Badinutti* says that in India, about eight miles from the town of Jabalpur, is a place called The Bee, from the fact that swarms of the insects live there and defend their holding against the world. Shocking are the tragedies which have resulted from invasion of the spot. Some men who had unwittingly disturbed the bees were set upon by stinging millions, and plunged into the river. But every time they showed their heads above water, the insects settled upon them in clouds, and they chose drowning to a more hideous death. Deer, pigs, and even the lordly tiger, have paid the same penalty for their indiscretion. Says the Englishman who described the spot:

I determined to invade the home of the bees, and I began by designing a suit of defensive armor. It was a sort of overall suit, tied round the neck with tape, a bee-veil to be tucked into the garment, riding-boots, gauntlets, and two pairs of gloves. Into this suit I was sworn by the tailor, so that there should be no chink or crevice.

Abram, a native, and I, armored and carrying a bucket and two coils of rope, were to climb up to the back of the hills so as to get above the bees, and Percy, who was in charge of the boat, ascended the rocks. He went to the bank of the river, which was under the point of attack, and made his boat fast.

Abram and I climbed to a well-considered height, and then I left him and crawled cautiously forward. I could hear a sort of all-pervading hum, dominating even the roar of the water beneath, and my nostrils were filled with that sweet smell which is made up of honey, wax and pine.

I decided that the point of attack was about

a hundred yards farther on; so I returned for Abram, and together we made our way there. The cliff was sheer, and even overhanging. A dense mass of bees and comb lay about 50 feet below me, and 50 feet below that were the boat and my faithful ally.

I put one end of the rope round a tree growing at the edge of the cliff, gave the other end to Abram, and went over. I found I should have to get a swing to reach the ledge on which I meant to stand. Hanging down from this ledge from above was 10 or 15 feet of comb.

I reached the rock with my hand, gave a push, swung out, then in again, struck in the middle of the comb, and gained my feet with a scramble.

The bees were upon me. The air reeked with the curious acrid smell familiar to those who have been stung. The noise of the water below was drowned by the hiss of the angry bees. I was completely blinded, for they swarmed over my veil, blocking out the light. When I touched my body it seemed to me, through my glove, that I was covered by thick, soft fur, all bees.

For a few moments I was stupefied, frightened. Then I realized that my armor was trustworthy, and that I was safe. Abram lowered the bucket, and blindly I felt about for the comb, and as well as I could, scraped it into the bucket. I lowered it to Percy, and shouted to Abram to lower me. He told me afterward that he could not see me. In the place where he knew I must be was nothing but a brown, whirling mass.

I swung out into the dark, bumping as I went. At last a man clutched me, and I knew I was at the bottom. I brushed the bees from my veil, and through a driving mist of them saw a cluster of other bees in the shape of a man. This was Percy.

We cut ourselves adrift, and rowed to a convenient place, where we made for the shore. There, five mile away, we made a sulphur smoke, and were freed from the last of our enemies.

Our dresses had held, none of us were hurt, and we had just 15 pounds of honey. For that, three of us, for six hours, we held our lives in our hands.—Youth's Companion.

Standard Belgian Hare Book!

BY M. D. CAPTS.

THIS book of 175 pages presents a clear and concise treatment of the Belgian Hare industry: its growth, origin and kinds; the sanitation and construction of the rabbitry; selection of breeding stock; care of the young, feeding, diseases and their cures, scoring, marketing, shipping, &c. First edition of 50,000 copies was sold in advance of publication.

Price, in handsome paper cover, 25 cents, postpaid; with the American Bee Journal one year—both for only \$1.10.

The Bee-Keeper's Guide;

Or, Manual of the Apiaary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without *THE BEE-KEEPER'S GUIDE*.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW SUBSCRIBERS for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

A Home in Colorado FOR SALE

I have a fine Fruit-Ranch of 14 acres here at Fruita, all set to fine fruit, principally winter apples, with plenty of small fruits, peaches, pears, plums, cherries, apricots, prunes, and about 700 grapes; 100 colonies of bees, mostly Italians, and about 100 fine Belgian hares that I will sell with the place. The orchard is in fine bearing, being about 10 years old, and is clean and free from weeds. The house is a good 7-room one, nearly new, with bath and water; a good new barn for two horses and two cows; good brick hen-house and two good cellars, good lawn and shade. I have a pull-up water-right with the place, with an abundance of water at all times for irrigation. I am desirous of making a change in my occupation, and will sell the place at a bargain. With the proper party the yield from the place this year will be about \$2,000. It joins up to within 20 rods of the town site of Fruita, where we have one of the best high schools in the State, employing 7 teachers. It is only 1 1/2 miles to the depot, churches, school and post office, and has telephone connections with all parts of the State. This is a good, healthy climate, and good society.

Address for terms and further particulars,
J. C. CARNAHAN,
Box 64, FRUITA, MESA CO., COLO.

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers one ounce of the seed for sending us ONE NEW subscriber to the American Bee Journal for a year with \$1.00; or will mail to any one an ounce of the seed and the American Bee Journal one year—both for \$1.30; or will mail an ounce of the seed alone for 50 cents. As our stock of this seed is very small, better order soon.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 1.—Market is nominal in almost all lines; a little comb sells at 15c for choice white, with the amber grades ranging from 20c less. No movement of any consequence in extracted, all dealers seeming to be expecting a lower range of prices. A 1 lb. fancy white clover and basswood sells at 70c, depending on flavor, quality and quantity taken; ambers, 65c; dark and buckwheat, 55c. Beeswax steady.

R. A. BURNETT & Co.

DETROIT, May 31.—Fancy white comb, 14/15c; No. 1, 13 1/4c; dark and amber, 10 1/2c. Extracted, white, 6 1/2c; amber and dark, 5 1/2c. Beeswax, 27 1/2c.

Very little desirable honey in sight. The new crop will find the market well supplied. The demand is always light at this season of the year.

M. H. HUNT & SON.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from 1/2 to 1 cent.

C. H. W. WEBER.

BOSTON, May 21.—The market continues dull on honey with very light stocks on hand. Our normal prices are as follows: Fancy 1-pound cans, 17c; A No. 1, 16c; No. 1, 15c; No. 2, 12 1/2c. Extracted from 10c to 12c.

BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00.

PEYCKE BROS.

NEW YORK, May 3.—We report quiet market on all lines. While the old crop of comb honey is well exhausted, still there is some arriving, which has been carried by the producers so recently, for a higher price. Values are fancy nominal now, and it is only a first-class fancy article that will sell at quotation prices. We quote: Fancy white, 15c; No. 1, 13c; amber, 11 1/2c; buckwheat, 10 1/2c. Extracted is decidedly dull, and very little inquiry. Old crop of California light amber and partly white, is now being offered as low as 45c a pound for the producer, which, of course, hurts the sale of other grades to a large extent. Beeswax is firm and sells on arrival at from 20c to 22c.

HILDRETH & SEGLEEN.

ALBANY, N. Y., June 1.—Honey market quiet. No stock, no receipts, no demand now. It is between seasons. We look for good prices the coming season, for in this vicinity the foul brood has nearly exterminated the bee-keepers.

H. R. WRIGHT.

BUFFALO, May 29.—Very light trade in all grades of honey. Strictly fancy sells fairly, at 14 1/2c; dark dull at any price, and 50c to 60c the range. Beeswax, fancy, 27 1/2c; dark, 23c to 25c.

BATTESON & Co.

KANSAS CITY, May 4.—Practically no shipments arriving, and very little selling. We are getting \$3.50 to \$3.00 per case of 24 sections No. 1 white; amber, \$3.00 to \$3.25.

W. R. CROMWELL PRODUCE CO.,
Successors to C. C. CLEMONS & Co.

SAN FRANCISCO, May 22.—White comb 11 1/2c; 12c; amber, 10 1/2c; dark, 8 1/2c. Extracted, white, 5 1/2c; light amber, 4 1/2c; amber, 3 1/2c to 4c. Beeswax, 28c.

Market presents a weak tone, with dealers, large and small, holding off as much as possible, in anticipation of liberal offerings from producing sections at an early day. There is not much new honey now here, either comb or extracted. For some very choice white comb 13 cents is asked. New amber extracted has been placed at 4 cents, which is the utmost figure obtainable in a wholesale way in the local market for this grade.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of the buttons as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

Mr. W. J. PICKARD, of Richland Co., Wis., called on us recently, and reported quite discouraging prospects at present in his locality. Their 400 colonies require feeding to tide them over until the basswood flow.

Mr. HYPER ROOT, who so faithfully and successfully managed the stereopticon at the Chicago convention last fall, will have charge of the exhibit of the A. I. Root Co. at the Pan-American Exposition. He is the youngest of the A. I. Root family, we believe.

THE W. T. FALGOSER Co. and the A. I. Root Co. will have exhibits at the Pan-American Exposition, in the Agricultural Building. These exhibits will be conspicuously placed in the gallery, this gallery being reached by means of a traveling sidewalk. The two exhibits are placed together in the same booth, as it were, facing each other.—Gleanings in Bee-Culture.

OPPOSERS OF LONG-TONGUE BEES.—One of our subscribers writes that it is a "silly statement" that some bees' tongues are longer than others, but it may turn out to be a very important thing for bee-keepers, and then there may be some unpleasant eating of crow. One curious thing is that the bitterest opposition to long tongues comes from the same quarter where the most frantic efforts have been made to get bees from India just because they have longer tongues. Long tongues may not be of any consequence, but then they hurt. Let us wait and see.

MR. R. G. HAYN is one of our far-away Washington subscribers. When sending us the nice picture of his apiary, shown on the previous page, Mr. Hayn wrote us as follows:

I am 70 years old, and have always led an active and laborious life. Several years ago I gave up the ranch to my two sons, and that left me nothing to do, which I consider a bad thing, even for old people. In looking around for some sort of employment suited to age and acquired habits of life, bee-keeping seemed to be the thing. First, because I dearly love it, and second, because it would make me financially independent.

Several attempts had been made to introduce bees into this (Kittitas) valley, but each had proven a failure, and I was the first one to succeed in getting them to winter all right, and in securing a fair yield of honey. Our honey is of the finest quality when one knows how to secure it. Our first yield in the spring is mainly pollen from willow, then we have fruit-bloom and dandelion, and our surplus comes from white clover. After that there is not much to be gathered, unless one has long-tongued bees that can work on red clover.

I want to keep from 40 to 50 colonies, in S-frame Simplicity hives, and get an average yield per colony of between 40 and 60 pounds, spring count. There are three drawbacks to the bee-business here, namely, excessive swarming, dampness and mould in winter, and a poor market for our honey, our market being flooded with cheap honey from outside. When I first started in the business I produced chunk honey, then I changed to section honey, and now I am producing extracted

honey, which candies almost immediately after being extracted.

I believe that swarming can be partially checked by giving plenty of ventilation. I do this by inserting blocks between the hive-body and bottom-board, making the space one inch to begin with, and enlarging it as the season advances, until sometimes there is a 3-inch opening in front. Then in real hot weather I give ventilation at the top.

I extract before the combs are all capped over. Honey from fruit-bloom and dandelion is a little strong, and somewhat bitter. This honey, when extracted, soon candies, and I let it candy as hard as it will, then melt it by setting it on the stove in a vessel of water, heating it pretty thoroughly, then set it away until it again candies, when I repeat the operation, and set it away in open cans covered with netting to keep out the flies, and it is not long until I have a very fine quality of honey that sells readily, and gives good satisfaction. I peddle my honey in the home market. At first I had trouble in selling it, as nearly everybody was afraid of adulteration. But as soon as people came to know me, and that I produced the honey in my own apiary, the adulteration scare helped me to sell it.

One day I opened a jar of honey for a lady's sample, and found a bee's leg in it. Several children were standing by, and I said, jocosely, "You see this genuine honey because there is a bee's leg in it." I made the sale. I went up the street a little further, and when going to one house a little girl from the group came running into the yard, screaming, "O mamma, come quick; here is the man with genuine honey with bees' legs in it!" R. G. HAYN.

THE BEE-KEEPERS' SOCIETY of Erfurt, Germany, will hold its 50th anniversary this summer. An interesting exhibition is planned in connection with this convention or celebration. Bee-keeping of a hundred years ago is to be shown. One hundred and fifty colonies of bees will be on the ground, which will be prepared and started for the health in Thuringia at the close of the festivities. A portable apiary of 20 colonies (wanderwagen) will also be on exhibition.

Mr. F. Greiner reports this in Gleanings in Bee-Culture. The oldest bee-keepers organization in America is only about 30 years old, and it has had its name changed several times though only "married" once, we believe. The next meeting will be held in Buffalo, Sept. 10, 11 and 12. Are you going to attend?

MRS. GEO. JACKSON, in the Bee-Keepers' Review, speaks thus about boys and girls taking up bee-keeping:

"I, too, believe that bees combine best with bees; therefore, get more bees. If you have children to help, keep more bees. Bring up your boys and girls in the business. Have them work, study and think, the same as they would do in preparing for any other profession or trade, for it is distinctly a business of itself, and a paying one, too. Then, why let your young folks leave home? Have plenty of out-apiaries; plenty of profit. I believe there is a better opening in bee-culture to-day for a young man or woman than in almost any other line. It is equally good for girl or boy."

ADVANCED EGGS.—An amusing mistake occurs in the Progressive Bee-Keeper. A subscriber asks how soon after a swarm has issued it will be advisable to take away the queen to let the colony rear a queen. The editor replies not to disturb the old queen till four frames are filled with eggs, that in this case some of the eggs will be far advanced; that some think that such advanced eggs as the bees would choose will not make the best queens, etc. Of course, larvae were meant in place of "advanced eggs."

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., JUNE 13, 1901.

No. 24.

* Editorial. *

Swarthmore's System of Queen-Rearing, as given on another page, is well worth a trial. The part that costs, as he well says, is the part after the young queen emerges from her cell up to the time she commences laying. If Swarthmore's plan proves a practical success—and it certainly has a promising look—it will require a much smaller force of bees than has heretofore been used during this expensive period, and it is the size of that force that has caused the expense. It is given now in good time for a thorough trial.

A "Large Force" of Bees—What Constitutes It?—Speaking of strong colonies, the editor of *Gleanings in Bee-Culture* said, "By a 'large force' I mean a colony the bees of which will weigh 8 or 9 pounds, or what would aggregate in numbers 40,000 to 50,000." Dr. Miller replied:

"Are you not a little modest, Mr. Editor, in demanding only 40,000 to 50,000 bees for a 'large force'?" L. Stachelhausen says, "I have, in large hives, many times observed that the queen had laid, during the previous 21 days, 3400 eggs daily, on an average." Three weeks later about all the bees from that 21 days' laying ought to be on hand, making 71,400. If we count the life of a worker six weeks, then there ought also to be present bees from the eggs of the preceding 21 days. Say the queen during that time laid 2900 eggs daily, and allow that half that number had been lost by fatalities, we should have 21,000 to add to the 71,400, making 92,400 in all. Perhaps that is not often reached, but I suspect it is nearer the right mark than 40,000."

That answer seems to be carefully built, and yet it is only reasoning that such a number of bees ought to be present, which is a different thing from citing a case in which such a number of bees *has been* present. Editor Root returns to the charge by citing actual cases. He says that when they bought swarms by weight the average weight was 5 or 6 pounds, and some tremendous swarms that had to be hived in a two-story chamber weighed from 8 to 8½ pounds. As 8½ pounds at 1500 to the pound would make 28,250 bees, he thinks his estimate of 40,000 to 50,000 none too low. He thinks the Doctor wrong in assuming that all eggs laid by the queen are matured as bees, because bees certainly in some cases destroy eggs, and he says: "I should think we would be safe in saying that out of 70,000 to 90,000 eggs laid by a queen, we could not expect over 40,000 or 50,000 bees." The Doctor, in reply, questions whether eggs are destroyed by bees unless queenless, and the editor closes the

controversy by challenging the production of a colony of bees that will weigh more than 9 pounds, equivalent to 40,500 bees.

There are two questions of fact in this controversy that it would be interesting to have settled. What is the largest force of bees that may be secured as the progeny of one queen? That ought not to be a very difficult thing to determine by actual weighing. Certainly it ought not to be difficult to determine whether 40,000 or 90,000 is nearer the right mark. The other question may not be so easily determined. Is it true that of all the eggs laid only 56 percent mature as bees? If it is true, it would seem a very wasteful thing. But if a queen lays 3000 eggs daily for six weeks, and her colony weighs only 9 pounds, it is hard to get away from the conclusion that nearly half the eggs have been wasted.

Moving Bees Together for Winter.

—In the *Bee Keepers' Review* is given a picture of an apiary of E. B. Tyrral, the space between the hives in a row being just enough to allow another hive to be placed between, the object being to move the two rows together into one solid row for winter. Before packing the bees for winter the two rows are now moved together, a little at a time, one row being moved backward, the other forward. Of course, this takes only about half the labor, and very much less than half the packing material it would take if the two rows were allowed to go through winter as in summer.

Here is another way that gets them into still more compact form:

```

OO OO OO OO OO
OO OO OO OO
OO OO OO OO
OO OO OO OO

```

Here are 36 hives in four rows, and, of course, the rows could be continued to any length. The first row of 10 hives and the second row of 8 hives both face the same way—toward the top of the page. The third row of 8 hives and the fourth row of 10 hives both face the same way—toward the bottom of the page. That makes the central two rows stand back to back. When winter approaches, the first row is gradually moved back until in a straight line with the second row, and the fourth row is moved back in line with the third row, the four rows now standing in two rows thus:

```

OOOOOOOOOOOOOOOOOOOO
OOOOOOOOOOOOOOOOOOOO

```

Food of Queens, Drones, and Larvae.

—Among American bee-keepers there is a feverish anxiety for immediate results, and

they pride themselves on being intensely practical, but they would have better success in the long run if they would take the trouble to inform themselves upon some of the elementary matters that have been carefully sought out by scientific men, especially in Germany. In the *Progressive Bee-Keeper*, L. Stachelhausen gives in a succinct manner some things about the prepared food which although by no means new, are probably new to the majority of bee-keepers. Asked whether at the time of contemplated swarming the workers withhold from the queen the egg-producing food, he leads us up to an affirmative answer by giving the following information:

The queens and drones never eat pollen, but are fed chyle by the workers, which is fully digested pollen, and is identical with the blood of the bees. They may also help themselves to honey, which is fully digested nectar. So the queen does not digesting, being entirely dependent upon the workers. This freedom from the burden of digestion, and being fed so freely with food that is concentrated and nourishing, explains how it is that a queen, whose body without eggs weighs only 0.20 grains, can lay in 24 hours 3000 eggs weighing 0.60 grains, or three times the weight of her body.

The larvae receive quite the same food, that is, chyle regurgitated from the stomach of the worker-bee. Nevertheless, we find the necessary difference in nourishing of the different kinds of larvae. Queen-larvae are supplied with pure chyle till the cell is capped in large quantities; we call this food "royal jelly." Worker and drone larvae receive the same chyle during the first three days only, afterwards the food is less digested by and by, and we call this food chyme. From the fifth day, till the cell is capped, honey and pollen is fed to worker as well as to drone larvae."

Michigan Bee-Keepers will serve their

own interests if they will read the following, and follow the suggestion made:

TO THE BEE-KEEPERS OF MICHIGAN:—

I take this method of informing the bee-keepers concerning a few points in regard to the Michigan foul-brood law.

A locality must be reported to the Dairy and Food Commissioner, Lansing, Mich., before it can be inspected, and as our funds are limited it would be a great saving if the bee-keepers would work with the inspector by reporting all localities where foul brood exists, or where it is thought to exist, as soon as possible. If this is done, it will enable the inspector to plan a trip through the State and cover the whole territory to be inspected at a much smaller traveling expense. Localities first reported will receive first attention, and those who neglect to report their localities until late will in all probabilities be obliged to wait until next year for assistance.

JOHN M. RYKIN, Inspector.

Early or Late Requeening of Colonies.

BY C. P. DADANT.

MR. C. P. DADANT: In the American Bee Journal of Feb. 14, I had an article, one paragraph of which related to the introduction of queens in the fall. I said that I requeened one-fourth of my apiary last fall, and that most of the work was done in October, and the early part of November. I also said that one reason why I liked to do this work so late in the season was because the colonies were in almost every instance broodless—the printer made me say "too deep" for broodless, and that because the bees had no means for starting queen-cells I did not have to be so particular about the time of giving the new queens. I had requeened some broodless colonies as late as November in years before, and did not see but that they did as good work the following season as any other colonies in the yard.

On the same page, 102 are given Dr. Mason's views regarding the best time to requeen an apiary. He says that just as the honey-flow is closing up, and before it closes, is the best time to requeen an apiary, and gives as a reason that the bees must have the vim and energy they have when the honey-flow is on.

Now, if I am very much in error in preferring to do the work later in the season, I would like to know it, and the reason why.

I write this to request that you give your views and experiences on the subject of the best time to requeen an apiary, in the columns of the American Bee Journal. I want particularly to know what disadvantages, if any, result from late requeening? EDWIN BEVINS.

Perhaps I am hardly fit to pass an opinion. I will frankly acknowledge that I never did but once change queens in any of my colonies late in the season, either during or after the flow. I have always allowed the bees to do their own "requeening," except in cases where the queens were infertile or of impure blood. At the time when we were breeding Italians for sale, this had quite an importance. But since we have been keeping bees only for honey, we have had less reluctance in allowing the impurely mated queens to live, if they are prolific. My reasons for not requeening an apiary, when the queens become old and possibly near their decrepitude, date back a good many years. I will have to tell you how this came about.

The much lamented Mr. Quinby, about 1808 or 1870, invented what was called the "queen-yard." It was a shallow square box, set in front of the alighting-board of each hive, walled with tin about four inches high, and with a tin edge projecting inward horizontally all around, to prevent swarming. The queen's wings were clipped so that she could not possibly jump over the walls of the queen-yard, and as the tin projection prevented her from climbing out, she was practically a prisoner in the front yard of her own hive. This was securing the same result which is now secured with the queen-trap, but with the greater convenience for the bees, of having nothing in the way of their flight or of their free access to the hive for ventilation, etc. The only objection was that the queen's wings must all be clipped.

We used this queen-yard largely, and it was owing to this method of clipping queens' wings that we ascertained how readily the bees would supersede their old queens without the knowledge of the apiarist. Often, yes, in many cases, we find that the clipped queen had been replaced by a younger one, without our even suspecting the change. And yet, at that time, we were very prone to examine the hives from end to end on the slightest pretext. We spent more time then on one hundred colonies than we would think of spending on 400 to-day. But I must say that it paid, in dollars and cents; for the extra attention was rewarded by extra results.

The reader will now perceive why we did not practice requeening. We found that in many instances we might be destroying young queens which the bees had reared in anticipation of the old age and failure of the mother.

But requeening is certainly a very good method, if it is not carried to extremes, for inferior stock may thus be replaced by selected stock from the very best colonies. Only I would not limit this to any particular moment, but would do it whenever I had a stock of good queens to spare.

The methods pursued by Dr. Mason and Mr. Bevins, as mentioned at the head of this article, both have their good points. The only objection that I can find to that of Mr. Bevins is the possibility of a shortage of drones, if we wait till the season is nearly over. One time, years ago, we had occasion to sell ten tested Italian queens after the end of the harvest, some time late in October. We had no

queens except in full colonies, but as the price was high, we did not hesitate to remove that number, expecting the colonies to rear young ones, and they did. But by the time our queens were ready for fertilization the drones must have been too scarce, although we had taken pains to keep all we could in a few queenless colonies, for not one of our young queens was fertilized, and the following spring we had ten drone-layers of the very best quality in ten of our very best colonies. And, by the way, let me here remark that this is a very good way to have early drones. We took advantage of this to rear early queens, and they were all purely mated before the impure drones hatched in our neighborhood. The possibility of the queens failing to mate seems to me to be the only really strong argument against requeening an apiary late in the fall.

There is perhaps another objection arising from the difficulty of manipulating hives much in cool weather, and when robber-bees are as alert as they generally are at that season. But these objections fail to embarrass a practical apiarist, because he will take his time, and use enough precautions to avoid disturbances. In out-apiaries, however, where a man can give his personal supervision only at times, I should not like to do much of this handling after the honey crop has ended.

I would suggest that the most economical plan to requeen would be to rear queens more or less during the entire season, and requeen as we go. If, however, we choose to do it all at one time, I would hardly wait till all the brood was hatched out, unless the season was particularly favorable, and we could make sure of securing a sufficient number of drones as late as desired. Since Mr. Bevins has succeeded, it shows that the thing can be done, and it has the advantage of not disturbing the bees during the crop. If the queen is removed before the end of the harvest the brood that hatches out will give room for honey in the brood-chamber, and quite a portion of the crop may be placed there, out of the reach of the apiarist, unless he resorts to the extractor. Hancock Co., Ill.

Scientific Names—Mellifera Not Mellifica.

BY PROF. A. J. COOK.

WE have all become used to the name, *Apis mellifica*, to designate the honey-bee. Some will wonder why we change to "*Apis mellifera*." The specific name in both cases comes from the root for honey, and either would seem appropriate. Why, then, give up a name which has been so long in use, for one no more apposite, and which is an entire stranger to us?

Our present method of naming animals and plants was originated by the great Swede, Linnaeus. It is called the binomial system of nomenclature, as two names are always used in designating plant or animal. Thus we have the generic name and the specific name. In the honey-bee the generic name is *Apis*. This is broader in its significance than the specific name. We have *Apis dorsata*, the great bee of India, as well as the ordinary honey-bee, of which, as we well know, there are many races.

The specific name, on the other hand, refers to only one kind of bee. All the individuals of a species will be very nearly alike. Where any species is placed under varied conditions the individuals will tend to vary, and thus we have what are known as races. In our domestic animals, where man places them under such very different circumstances, they will vary much more than they would in nature, and so races are very common among our domesticated animals.

I think the races of our bees—Italians, German, or black, etc.—were generally formed by nature alone. The races will have habits and general peculiarities that are much more similar than will the different species. I think, too, they will be more apt to vary in their own characteristics. Our dogs and horses are good illustrations of the variations often seen in our domesticated animals. All dogs are one species—*Canis familiaris*. Yet how different are the poodle and the Saint Bernard, and how numerous and how varied are all the intermediate breeds. Our horses, likewise, are one species—*Equus caballus*. We all know how wondrously different are the individuals of the horse species. The Shetland pony and the Norman well illustrate what a different environment with careful selection may do in modifying a species. The old idea that only animals of the same species would interbreed was found to be untrue. The mule—a cross between the donkey and the horse—two obvious species—made it necessary

to modify the old notion. But as we all know, the mule is infertile. It was then stated that only animals that would interbreed and the offspring prove fertile belong to the same species. I think this is pretty generally true among the higher animals. But I think there are numerous exceptions among the lower plants and animals. I think there are cases on record where different genera interbreed, and the offspring are fertile. Of course, such cases are very rare.

As we understand from the above, the nature of a genus and a species, which may be better understood by comparing them to our own names, the genus standing for our surname, and the species for the given name, we are now prepared to discuss the change of name in the honey-bee. This change of names, not only of insects but of all plants and animals, is very common. I know of some insects where the names have been changed two, three, or even four times during the last few years. It comes about in this way:

Two or more persons describe the same insect or other animal. Of course only one of these names can be selected. It has been decided that only the first name should be adopted. It is unfortunately true that sometimes the first name and description appeared in some obscure publication and were for a long time unknown. Therefore the second, third, or even fourth name was for a long time used in speaking of the insect. After a time, it may be for years, some one discovers the name and description, given third in order, we will say. Of course the old name gives place to this. Afterwards the second one may replace this, and finally the first and rightful name is unearthed and manifestly this takes precedence of all others. It is obvious that this frequent changing of names is a great hindrance to science, and a tremendous annoyance to the student: yet it is certainly the lesser of two evils.

It is now stoutly urged that every first description of an animal, where, of course, the name will be given, be published only in some standard scientific paper that every student of the science may have ready access to it, and may know of its existence. It is also equally important that every person in naming an insect and describing it take all possible diligence to make sure that the same species has not been previously described.

The father of this system of naming, who may almost be said to be the father of both botany and zoology—Linnaeus—was the first to describe our house-bee. He described it as *Apis mellifera*, and so, of course, this name has priority and must be accepted. Three years later, he described the same insect again under the name *Apis mellifica*, the name which has been used ever since. It is strange that the same person should describe the same insect twice under the same name, yet when we remember the amount of work Linnaeus did, and the astounding number of descriptions he made, it is not strange that he should have forgotten that he had made a description, and so should have named and described the same animal or insect a second time.

It is to be hoped that all our bee-papers as well as writers, will make a point of bringing this new name prominently forward, that very soon it may seem as right and natural as the old one. We are certainly fortunate in the name, which means honey-bearing. This name, then, will suit those nervous people who proclaim in the face of the truth that the bee simply gathers honey and does not produce it. The name is the truth maligned in this new name, for although honey is gathered in a stirred product and so is produced by the bee, we can still say that the honey-bee is a honey-bearing insect.

So hereafter we will all unite in the name *Apis mellifera* for our pets of the hive. Los Angeles Co., Calif.

The Swarthmore System of Queen-Rearing.

BY "SWARTHMORE."

A GREAT deal has been written, said and done to simplify and cheapen methods for cell-getting, until now queen-breeders have about all that can be desired in an almost perfect system of cell-work, from the egg to the mature queen, her care after hatching, and all that. But cell-getting is not the expensive part of queen-rearing; in fact, it does not represent an eighth part of the work connected with the securing of a laying queen, ready for posting to the customer far or near.

The *great* expense in queen-rearing is that necessary for the proper fertilization of the young queens after they

are reared. The queen-breeder, heretofore, has been obliged to tear asunder large numbers of full colonies to form nuclei of a frame or two each to receive the young queens, each in a separate colony for mating purposes only.

Now, all this is expensive not alone in bees but in time, labor, care, and a hundred other ways. Full colonies are ruined, and all revenue from bees thus treated is entirely cut off until a laying queen is secured, sold, caged and mailed. All this woeful waste has set me to thinking about a plan of operation to lessen the expense and labor in queen-rearing at the mating period.

Some years ago I succeeded in mating a number of queens from x_1, x_4 section-boxes, each supplied with a tea-cupful of bees; but not until the past season have I been able to say that I have discovered a practical method of mating young queens by the section-box plan, although I have used them now for about 13 years.

The plan I have at last adopted is as follows: Hive a good-sized swarm (natural or forced) into a body containing ten all-wood or Simplicity frames, each frame filled with 4 $\frac{1}{2}$ x 5 $\frac{1}{2}$ x 1 inch one-piece plain sections, thus:

FRAME WITH FOUNDATION.

Each section should be supplied with a starter of brood-foundation, as shown, and the frames are set rather close together until fully drawn out by the bees. Unless honey is coming in rapidly the bees should be fed constantly during comb-construction, in the event of the swarm being a forced one.

In a few days a good, prolific queen will have filled the most of these little combs with eggs, and in due time it will be found that each little comb has its supply of brood, honey, and bee-bread—the exact condition necessary for the successful formation of nuclei for queen-fertilization.

At this point take away all the section-holding frames, supplementing them with full sheets of capped brood, honey, etc., taken from other colonies; put on the surplus arrangement, and close the hive. That colony will yet show you honey before the end of the season; even though you have borrowed every particle of their work from the time of hiving. Let them work on; you will not need to molest them more.

Remove the section-holding frames now clear of bees, just as taken from the hive, to the honey-house, and adjust

TOP OF FERTILIZER NUCLEUS-BOX.

A, lid; B, section box frame; C, C, C, live-staples, for guidance;

to each side of each little comb, containing brood, a cover made of the stuff, with $\frac{1}{4}$ -inch strips nailed all around the edges; as shown at A, Fig. 1. Four small staples, C C C C, driven part way into each corner of the lid, so as to project or telescope into the section-box, will serve to hold the lids in place until they have become glued a bit by the bees.

When the lids are all in place, each little comb will be in a compartment by itself, and each compartment may be entered by the bees through the perforated zinc that covers the two $\frac{1}{4}$ -inch auger holes in the center of each lid, as shown in the drawing, E E, Fig. 4. The zincs are nailed

FIG. 4.
BOTTOM OF FERTILIZER NUCLEUS-BOX.

Fig. 4 is a view of the under side of H, showing holes uncovered; B, part of section-box; E E, holes covered inside with perforated zinc; F, flight-hole uncorked; dotted lines show position of thin board when excluder-holes are covered.

fast to the inside of each lid. Pieces of section stuff do very well to close the zinc-covered holes when occasion demands (see dotted lines in Fig. 4). A $\frac{1}{2}$ -inch flight-hole is cut just below the two large holes in one lid only. This is stopped with an ordinary druggist's cork, which is easily drawn when queens are to be introduced.

Now run a perfect-winged and sound-legged young virgin queen into each compartment; then recork the flight-holes and expose the zincs on all sides so that the bees can readily enter all the compartments from the sides, yet no queen can leave the compartment in which it is intended to restrict her. Then hang the frames in the hives of such bees as you may have just used in getting a batch of cells, or any queenless and broodless bees you may have at hand. Be careful, however, that there is no sort of queen with them, virgin or otherwise; and if they have been over three days queenless, a little tobacco smoke should be used.

A very simple way of supplying the compartments with young queens is to attach a ripe queen-cell to each comb before adjusting the lids; then hang the frames among queenless and broodless bees with flight holes corked, and zincs exposed. The bees will at once occupy the compartments, and in due time a young queen will hatch inside each compartment.

Any queenless bees will soon enter the compartments, and care for the brood and queens; and as soon as they become settled, feeding may begin. Feed a little sugar syrup (no honey) each day; and at the end of the fifth, if the weather is fine, remove the frames carefully, bees and all. Close all the entrances so none can escape from the compartments. If the weather is very warm, cover the holes on the flight side with wire net, as shown in the

ALLEY CONFINING-SCREEN.

engraving, taking in as you do so, as many bees, that may be on the outside of the boxes, as possible.

Take these frames some distance from the old stand, and set them out separately on stakes driven into the ground, thus:

SWARTHMORE'S FERTILIZING-FRAMES, WITH NUCLEUS-BOXES IN PLACE.

Toward evening open the flight-hole to each compartment—three on one side and three on the other, as shown above by the letters F F F. If the next day or two be fine, each and every queen will leave its little chamber to mate, and just as large a percentage will return safely as by any method of nucleus management now in vogue. The life of these little colonies may be sustained several weeks by feeding lozenges of "Good" food every three to five days. Press the food into the holes at the back of each box. The blocks of Benton mailing-cages may be filled with "Good" food attached to the back of each compartment by two staples driven into the ends of same and hung on two cor-

TOP VIEW OF COVER.—G, food feeder.

responding wire-nails driven into the back lid, as shown in engraving at G, Figs. 2, 3.

Examinations for eggs may be made quite well through the back-most holes, which are easily uncovered by unhooking the Benton-cage feeders; and when it is found that the young queens are laying, they should be removed and other young virgins supplied; or the frames may be again collated and placed on a single stand where the laying queens will keep in good health for an indefinite period.—Gleanings in Bee-Culture.

Bees and Fertilization of Blossoms—Other Comments.

BY ALLEN LATHAM.

ON page 262, is an important as well as interesting article on the subject of bees and the fertilization of fruit-blossoms, by Thaddeus Smith. This article is bound to raise a controversy if not hot words. I hasten to put in my word in support of the writer in hopes to stem the wrath to come from the other side.

Provincetown, Mass., is the town at the extreme end of Cape Cod Peninsula. The land here is from one to two and one-half miles wide. It is swept by sea-breezes almost all the time. It is thus a poor place to keep bees. No bees at all are kept, as far as I can find. I have my summer cottage there, and in the two summers that I have spent there I

have not seen a single honey-bee. Right in front of my cottage is a fertile meadow in which the white clover stands nearly knee-high. Many bumble-bees may be seen on this, but not a honey-bee.

You naturally ask what this has to do with the matter which I began with. Just this—that region is extremely fruitful. Never have I seen small fruits in such abundance as there. Bushels of wild strawberries are gathered in June, while in July the shadbush berries fairly bend the bushes to the ground. There are blueberries, huckleberries, blackberries, raspberries, wild cherries, and last but not least, beach-plums. The shadbush berries, or Juneberries, or sugar-plums as they are known in many places, or as they are called in Provincetown, "juicy peaches," are the most wonderful fruit (unless I except beach-plums) I have ever seen wild. I left the cottage one day to get some for pies. I was gone less than an hour. I rode on my bicycle awhile, then walked one-third of a mile, then picked two five-pound honey-pails full, then walked and rode back. You can see from this how thick the berries are. I have seen the smaller bushes lying flat on the sand, dragged there by the weight of the fruit. One could easily gather a bushel in an hour.

But, oh, the beach-plums! The sand-hills are covered with the scrubby plum-bushes; and the bushes are loaded with the plums. The Portuguese women and children gather these plums by the bushel. The plums are about the size of cultivated cherries. I have seen a cluster of these plums that would yield a pint or more at two scoops of the fingers. One small bush the size of an ordinary currant-bush will often yield four or five quarts.

Now how do these fruits form if there are no bees there? I shall not attempt to answer that question. I merely state the facts as they are, and ask how it is done.

KEEPING QUEENS OVER THE WINTER.

The question, "How can I winter my surplus queens?" is often asked. Though I can offer no easy way of wintering a large number, I can tell how one or two choice queens can be saved. It not infrequently happens that a bee-keeper has an extra queen or two which he would like to winter. More than that, he can often profitably use such queens in the spring. Many a time have I had a fine, strong colony in spring queenless. Unless a queen can be given, that colony is not of much value. With a queen it will be ready for the June and July harvests.

Last fall I had two surplus queens of excellence. I could not think of killing them, but I had no colony without an equally good queen. I still have those queens in good health. I took from two strong colonies two frames each of brood with adhering bees. I placed these in a hive prepared as follows: A tight partition was put in the middle of the hive lengthwise, the partition extending into the portico of the hive. In each side I placed a cushion of such thickness as to allow two frames between it and the partition. The four frames spoken of above were disposed of in this way. I gave each side a queen. Most old bees flew back to the parent hives, only a pint or less remaining in each side.

The care of the hive was then the question. All through October and November (the nuclei were made in September) I either placed a heavy carpet over the hive on cold nights or carried it into the kitchen. The hive had been set close by the back door. On cold days the carpet was left on the hive. When settled cold weather came the hive was taken to the cellar and placed close to the hot-water heater with the entrance away from the light. Here it had a temperature of about 30 degrees. When a warm spell came the hive was put out so that the bees could fly. There were two months in which the hive was not touched. The bees did not get restless. They came through with small loss in numbers and are breeding up slowly. It so happens that none of my queens died last winter. I shall try to build the little colonies up. They were put out in March, being carried into the kitchen in cold spells. The entrances are provided with screens.

You say, of course, that this is too much bother. There is work in it, but it is that pleasant puttering work that every bee-keeper loves. More than that, it will save the lives of valuable queens, which in turn may save the existence of valuable colonies.

LONGEVITY IN BEES.

I am glad to see a word from Mr. Doolittle in regard to long-lived bees. Prolificity at the expense of strength has been too long the vogue. We have all had a colony occasionally that had its frames packed with brood. We

have fondly looked for great results. They did not come. The colony failed to gain in numbers though the frames were kept full of brood. All the honey gathered went into more bees—more *short-lived* and *worthless* bees. On the other hand, we have seen a colony with only five or six frames of brood. We have turned from it in disgust. Behold that colony a month later. Still only five or six frames of brood. But where did all those *bees* come from? They crowd the hive and they have stored two cases. Those are *long-lived* and *the right-kind* of bees. Let us rear that kind. I do not mind if they have ten frames of brood, but let the bees be long-lived.

I scarcely need to say more in favor of long-lived bees, but will offer a few more words. It is easy to see why these bees are of so much more value than short-lived bees. First of all they winter well, coming out strong in the spring, and do not spring dwindle. A single bee is worth two or even more of the other kind. Why? In the working season let the short-lived bee live six weeks, the long-lived one nine. Each costs the same to rear. One works from two to three weeks, the other from five to six. The short-lived bee is a *provider* about one week; the long-lived bee is a *provider* about four weeks. Do we not find the secret of a honey crop right here?

I have a colony that has bees which winter and then give noble aid in filling the first sections. I honor those bees. They are my pets. Norfolk Co., Mass.

No. 6.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

(Continued from page 343.)

NOW, see here!" began Mr. Bond. "I am not the least bit sure that I can remember all the things you have been telling me to-day; but I am here to learn all I can. You shut me off twice when I asked questions—or put me off, rather. Now, I'm going to ask some more questions, and I think you ought to answer them right on the spot."

"First, then, you've told me all about putting supers on this hive until you had five of them on, all in a pile. I'd like to know what you do that for. I can see no sort of sense in it. To me it seems like boy's-play to lift off and then lift back again a whole stack of supers weighing 28 pounds each. Now, tell me, if you please, what do you do such a cranky-looking thing for?"

"I am glad to have an opportunity to enlighten you on that subject, Mr. Bond," I replied. "But first I will inform you that the cranky-looking performance isn't boy's-play at all, in any sense of the phrase—surely not the lifting part of it; that you can readily see for yourself."

"You will not object to my using an illustration that must be familiar to you, in order to impress my answer to your question upon your mind so that it will stick. Well, you know that hens will always choose a nest to lay their eggs in which has at least one nest-egg in it—the more the merrier, in fact. They will generally avoid an empty, or an unused nest; and hence the fact has been generally accepted by poultry-men, and poultry-women, especially—that it pays to furnish the nests with natural or artificial nest-eggs. The women, at least, think that it encourages the hens to lay. I must confess, however, that I have never known a hen to lay more than one egg a day on that account. And I presume you can say the same, Mr. Bond."

"That I can," he replied. "But, for all that, I can't quite see the point where the illustration applies. Some illustrations don't illustrate, you know. I've heard lots of that kind, preached. But, of course, bee-keepers aren't preachers."

"Well, perhaps there is no point for you to see, and my effort is lost," I replied. "I shall therefore give you my answer ungarlished:

"The fact is no invention or discovery of my own, that bees will work better and carry in honey faster when they have lots of it stored in the hive. Bearing this fact in mind, it has become the regular rule with many bee-keepers to 'tier-up' the supers on their hives as fast as the bees fill them, and to take none of them off before the honey-flow is played out."

"Those who have been doing this, year after year, have become satisfied that it pays to do it; and that it doesn't pay to do otherwise."

"Of course, I am aware that there are bee-men who stoutly maintain that there is no difference; that they have

always been in the habit of taking the honey off the hives as fast as the bees finish the sections in the supers, and that the bees always begin to work promptly in the empty case, put on in place of the one that was removed. But, you see, such testimony doesn't weigh a feather, because it is one-sided; for, if those bee-men have never thoroughly tried both ways, they have no right to say that there is no difference.

"Now, Mr. Bond, I am fond of testing things, for the mere sake of the thing, sometimes. Hence, when I read about 'tiering-up' the supers, leaving them all on until the end of the honey-rush because of several reasons given, I at once tried it. But, in order to test the trial, I made a few experimental observations bearing on the questions. One of these was a case where one of my colonies had gone out on a strike, as it were. They, for reasons known only to themselves, refused to work. All the other colonies in my apiary were rushing the honey into the supers at a lively rate. Some of them had filled from one to three supers each, while this balky one had not even drawn out the foundation in the sections of the super on their hive. I had tried everything I could think of to induce them to 'get a move' on themselves, but without the result sought. It was a strange case, for the hive was full of bees—even the super was full during the day-time—and the eight frames were solid with brood and sealed honey.

"Well, sir, I don't now remember how the idea came to me—whether I dreamed it, read it in the bee-papers, or heard it related at a bee-keepers' convention—but, at any rate, I did this:

"I opened that hive one beautiful morning and took their empty super away from them. Then I took out two frames that had more brood than honey in them, and gave them to another colony, from which I took, instead, two frames nearly filled with honey, some of it unsealed, and put them into the hive of lazy bees. Next, I took out the frames that had the most honey in them, and with my honey-knife shaved off the capping, thus unsealing a large patch on each frame. This drastic proceeding set a lot of honey loose, of course; but it also broke up the strike. I watched them nearly the whole of that day, and I tell you, Mr. Bond, I had to laugh out loud to myself several times to see those bees hustle themselves to keep that loose honey from going to waste. Of course I was on the look-out all the while to prevent any of the honey from running out at the bee-entrance and tempting other bees to come and investigate matters.

"The next morning those bees went to work in the super, which I had replaced the evening before; and they didn't let up until the end of the honey-flow, when they had filled two supers, and a third partly.

"Another experiment I made—no, I beg your pardon, it wasn't an experiment, but an experience—and it happened in this way:

"Before I adopted the tiering-up system I always put on only one super at a time, and then looked through the glass in the side to see when the bees were sealing the outside sections. When I saw them do that I took that super off and gave them an empty one. Well, I had often before noticed, when I had performed this operation, that there was a very marked slacking-up of work in those hives from which I had taken full supers; but I did not stop to study about the cause. It was not until that same season when I learned how to break up a strike in a colony that I took particular notice of this streak of loafing, or sulking—I am not sure which it was.

"When I was taking off full supers one morning I found that one of the colonies had put in spare time in building brace-combs between some of the frames, and had extended that kind of work to the top of the frames, for I found that they had filled the space between the brood-frames and the bottom of the super almost solid with honey. Well, in taking the super off, this extra arrangement was of course broken up, and a lot of honey let loose.

"There were several important things about bee-keeping which I hadn't then learned yet, hence I was not aware of the fact that those bees did that extra job because they were short of honey-storing room for several days before I thought it was time to give them a fresh super. Thinking, however, that the extra comb had to be removed before a fresh super was placed on top of the frames, I took the honey-knife and bee-smoker and went at it. It was a sweet job of work, now I tell you! But I got through with it without getting more than a dozen stings on my hands; and then put on the super, and cheerfully closed the hive.

"While doing that little job of work, Mr. Bond, I

learned something that was new to me. When I first began slashing into the comb with my honey-knife I got quite a number of hot stings on my naked hands: As I proceeded, my hands became daubed with honey, and I noticed that the bees did not attempt to sting where there was honey. Taking the hint, I daubed honey all over my hands, with the result that I got no more stings doing that job.

"This recipe I throw in extra, without cost. You can tell by trying it—should occasion call for self-defense some time when you find it necessary to do such work—whether it will pay for the wasted honey or not. There are occasions, you know, when a bee-keeper can't keep his hands in his pockets and yet do the work that calls for their use."

(To be continued.)

Questions and Answers.

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller directly, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Building Up Colonies.

My bees wintered well—47 colonies out of 49. A few of them are very strong. What is the best way to build them up? Give them a frame of brood from a strong colony, or exchange hives in the middle of the day when the bees are flying the strongest? ONTARIO.

ANSWER.—Take from a colony that has five brood or more, leaving it only four frames of brood. Do not give these frames of brood to the weakest colonies at first, but give a frame to each colony that has only three frames, until these are all supplied, then give to the weaker ones. Take the adhering bees with the frame of brood, but be sure you don't take the queen. If you give more than one frame to any colony, let them be from different hives, for if you should give two frames with adhering bees from the same hive it would endanger the queen.

Filling Combs With Syrup for Feeding—Fastening Queen-Cups.

1. I am the newest and "greenest" of bee-keepers. On page 310, Allen Latham writes of filling brood-combs with sugar syrup from a coffee-pot at the beginning of the apple-bloom. How does he hold the comb during the operation—upright, as it is in the hive, or does he turn it from side to side?

2. In making queen-cups a la Doolittle, I suppose the bottom, i.e., the thickest part of the cup, is fastened to the stick, is it not?

3. My bees pay no attention to the syrup I try to feed them. How shall I get them to notice it?

MRS. BEE-KEEPER.

ANSWERS.—1. You are no greener than the rest of us have been, but are perhaps a little smarter in finding out sooner your greenness. You are very wise to pocket your pride and ask questions that may betray some degree of ignorance. When you do not find instruction in your textbook upon any given point, you may gain that instruction through experience, but sometimes that is expensive, and by asking questions you not only gain the desired information for yourself, but help others as well.

Mr. Latham gives no particulars, but you may be sure he does not have the comb hanging, as in the hive, when filling it. Lay it flat in a tub; pour the syrup into it from a height of three or four feet, and the fall from such a height will make the syrup force its way into the cells. It will work better if the syrup is hot, but you must look out not to melt the comb. When one side is filled, turn the comb over and fill the other side. Then hang the comb in a hive-body that stands over something to catch the drip.

Years ago I fed many gallons of syrup in combs, and to make the work easier I had hung three or four feet above the tub a large baking-powder can, or something of the kind, the bottom of the can being punched full of nail-holes, the holes being punched through from the inside.

With a pitcher in one hand I poured the hot syrup into the can, while the other hand kept the can moving about over all parts of the comb. Having the can thus suspended by strings made it much easier.

2. Yes, mouth down.

3. Generally there is no trouble in getting bees to take syrup whenever they can reach it. Perhaps it was too cold weather for them to leave the cluster. Sometimes they will take hot syrup when they will not take the cold. The nearer the cluster the surer they will be to take it. If put in combs they will be sure to take it. For fear of starting robbing, don't give the combs till nearly dark.

Probably Superseded the Queen.

I have a colony of black bees to which I introduced an Italian queen last July, and in the fall they were mostly yellow bees, but this spring they are almost as black as ever. What is the cause of that? MINN.

ANSWER.—It is quite possible the bees may have superseded the Italian queen with one whose progeny is darker. It is even among the possibilities that a queen from outside may have gotten in, but such a thing is not at all probable.

Material for Cell-Cups—What to Feed to Work Them Up.

1. In making cell-cups for queen-rearing, what is the wax mixed with?

2. In the dry season when the bees will not work up the cups, what is best to feed them so as to induce them to work them up? JAMAICA.

ANSWERS.—1. The wax is not mixed with anything, but used pure.

2. Nothing is better to stimulate bees to work than honey, unless it be a mixture of honey and pollen. In the absence of this, a syrup of sugar does very well.

Dividing for Increase.

1. I don't care to let my bees swarm. Would it be safe to take one, two, or even three frames of brood from each hive, and when I get 10 frames put them in a hive, making sure that I have not taken a queen from any of the hives? Does it make any difference if there are any bees on the brood-frames? Do you think the bees would fight with each other, because there will be bees from different hives, such as Italians, blacks, and Hybrids, or would you brush the bees off when you take out the brood-frames?

2. What would I do for queens for each new colony thus made? COLORADO.

ANSWERS.—1. It will be safe to take one to three frames of brood from each strong colony so far as those colonies are concerned, but very unsafe for the brood if you take no bees with the brood. Even if you take with each frame all the adhering bees, all but the youngest will return, and you may not have enough bees to protect the brood. There will be no trouble as to bees from different colonies fighting if this is done when honey is yielding well. But taking one, two, or even three frames of brood from a colony of bees will by no means make it a sure thing that there will be no swarming. To make sure that there will be no swarming, you must take all the brood away. One way is as follows:

Suppose two colonies, A and B. Take all the brood from A, brushing the bees back into the hive, and replacing the frames of brood with frames of foundation. To prevent the bees from being too much dissatisfied, leave one frame of brood, to be taken away a day or two later. Put these frames of brood into an empty hive, and put it on the stand of B, putting B in a new place. This should be done early in the day, the earlier after bees are flying the better, unless you take the time when bees are having a play-spell after dinner, which is the best time of all. For a day or two all the field-bees of B will return to the new hive. A will not swarm, but the case of B is not so sure.

2. You can buy untested queens for a reasonable amount, and you will do well to have your queen on hand before forming your new colony. Or, you can in advance rear queens as instructed in your text-book. If you have no good text-book on bees, by all means get one at once and make a thorough study of it. It is hardly a safe thing to do much in the way of artificial increase without some knowl-

edge of the whole field of bee-keeping as given in the bee-books. Even if you have explicit instruction just what to do, some unforeseen incident will occur, and if you have no general knowledge of the subject some little thing may knock all your plans endwise.

You will do well carefully to examine back numbers of this journal also. See pages 345, 328, 312, 297, 264, etc.

Convention Proceedings.

(Continued from page 357.)

Report of the Minnesota Bee-Keepers' Convention.

BY DR. L. D. LEONARD.

SECOND DAY—FORENOON SESSION.

The first thing on the program was Pres. West's address, read by Mrs. Acklin, as follows:

PRESIDENT'S ANNUAL ADDRESS.

The Minnesota Bee-Keepers' Association was organized at Minneapolis about eight years ago, by a few determined and loyal bee-keepers, under the laws of Minnesota. Wm. Urie, Wm. Danforth, and B. Taylor, successful bee-keepers who have since passed to their eternal homes, were present at that meeting. There had been previous attempts made to organize, and meetings had been held; the Association got into debt, and was in bad repute. Under the present management the debts have been paid, and there is a surplus in the treasury.

Compared with other societies in importance, ability and influence for good, our Association stands in the front ranks. It is now a strong and vigorous society, having increased its membership, which includes some of the most noted apiarists in the West. When thoroughly organized the society at once took steps to put the honey department at the State Fair—which had become a disgrace to the bee-keepers of the State—under the supervision of honest bee-keepers. From that time until the present that department has gradually grown in size, quality and importance—in fact, no department of the State Fair has shown such marked improvement with the same amount of money expended.

Through the influence of this society a grand exhibit of the products of the little "busy bee" was made at Omaha, which demonstrated that the finest honey—as well as butter—comes from the grand, young State of Minnesota. The exhibit was a grand surprise to every one, and won great honors for Minnesota. Exhibits were made by some of our bee-keepers which scored 100 points.

Through the influence of this society a law was passed by the State legislature, making it a crime to sell or offer for sale adulterated honey, unless the package containing the same is marked, represented and designated as such. The enforcement of this law by the State Dairy and Food Commissioner has been of great benefit to the honey-producers of Minnesota, and his report upon this subject made in January, 1899, is quite elaborate. Our influence has also been felt among the commission men of the twin cities, and good has resulted therefrom for the bee-keepers of the State.

Organizations are necessary in all branches of industry, to protect and educate those engaged in such industry. No bee-keeper has arrived at that stage of perfection and success in his occupation where he can afford to dispense with the benefits derived from such an organization as this. Here we meet for friendly discussion and mutual profit.

The rapid advancement of apiculture during the past 50 years is in keeping with the rapid strides made in all other departments of life where genius and invention have been developed, due to the energy, enterprise, and self-sacrificing labors of such men as Father Langstroth, Moses Quinby, Adam Grimm, Capt. J. E. Hetherington, Lyman C. Root, Edwin France, Chas. Muth, H. R. Boardman, G. M. Doolittle, P. H. Elwood, A. E. Manum, Prof. A. J. Cook, Dr. A. J. Boardman, Dr. A. C. Mason, Chas. Dadant, D. A. Jones, W. Z. Hutchinson, Dr. C. C. Miller, A. L. Root, E. R. Root, and a host of others, whose bright and inventive minds and consistent lives have made, or are making, the bee-papers of to-day superior to the papers printed in the interest of any other line of business. What other branch of learning or occupation has had such honest, heroic, self-sacrificing, devoted and eminent workers? Their influence and superior qualities of heart and mind have blessed all other departments of life in

which they move. And what a pleasure it is on such an occasion as this to speak kindly of them, and to accord them a high place in our history!

Instead of the old straw hive and the log gum the invention and skill of Father Langstroth have given us the frame so admirably adapted for the home of the ever busy bee, wherein every kind of manipulation and theory are developed, and from which all other hives in a measure have been evolved. The large, unwieldy and unmarkable honey-boxes have given place to the white and beautiful one-piece section—a convenience and blessing to the apiarist, and which in its simplicity and cheapness is within the reach of all. From the swinging of the dinner-pail in which there was a piece of comb honey, around and over his head, by the ever restless and uneasy boy—which operation his father noticed threw the honey outward of the comb—came the honey-extractor now so generally used, a great help to every well-versed, for apiary, and indispensable to its success, as is also its companion, the honey-knife. Comb foundation, and the foundation-press by which it is made, are also great inventions, and universally appreciated by the successful apiarist.

Then comes the little queen-cage with candy—a great improvement and source of profit—a means by which the queen—indeed and in truth the most wonderful and interesting of all insects known—is transported from all parts of the globe, and we have this been able to improve our race of bees. The drone-trap, the self-hiver, the self-warmer, the queen-excluder, and the bodilite method of rearing queens; the honey-board, the wax-extractor, the queen cell protector, wired frames, the foundation-fastener machine, bee-feeders, bee-escapes, swarming devices, the smoker, the drone-excluder, separators, and the improved method of procuring comb honey; and very many other improvements and devices help to make the labor easy, successful and more profitable, and are valuable helps to energetic apiarists in some department of this most interesting occupation.

Invention, then, as we look at the old log gum and straw skep, and as we remember the sulphur pit where the faithful and innocent little creatures were murdered for their stores, in days gone by, has performed wonders for our occupation, and for the comfort of the noblest little creature which God has given to man.

The tendency of our occupation, then, like all other in such hands, is upward, and toward the light. This is an age of intense activity and progress—the tide is fast bearing us onward and upward. Some are wishing for the good old days gone long ago, but these are the best days since the stars first sang together, since the Messiah was found in the manger, and I, for one, am glad I am living now. Bee-keeping is wonderfully interesting and fascinating to the successful apiarist. It brings us in contact with one of the most wonderful little creatures in God's glorious universe. The man who is wise, happy and content, sees the eternal God in everything around him; the seasons, the fields, the hills and valleys, and all the creatures on the earth are clothed in glory; but nowhere, nor in any other creature, is the wonderful and all-wise adaptation and design manifested as in the little "busy bee." The manner and thoroughly practical government in the home, the power and adaptability of the queen with her body-guard, in that home for its good and success; the tiny eyes which she pover tires of depositing by the thousands until old age shall claim her; the care and attention of those eyes by the nurses of the family; the food and growth of the young bee from the time it begins to show life until its birth into that home; its care after birth; the different kinds of departments, and food which produces from the same mother the workers (neither male nor female), the drones (the male bee), and the queen, which produces respectively the worker in 21 days, the drone in 24 days, and the queen, much larger than the worker, in 16 days; the wonderful mechanical construction of the cell for strength and economy; the ability of the workers to gather nectar from the blossoms and flowers of the fields and trees, which, when stored in the home, becomes one of the best foods and medicines for man—I say all these traits of the bees, and many more that might be named, unfold a world of thought and investigation.

Honey has great healing and soothing properties, and is an excellent medicine for sore throats, lungs, cuts or sores of any kind. The poison of the honey-bee is an antidote for rheumatism. Dr. McDonald, of this State, informed me several years ago that he used the poison successfully for rheumatism and dropsy. Honey as food is very strengthening and bracing to the system. It is said that during the Russian and Turkish war in crossing the mountains the soldiers were weak and cold from lack of food. The Russian general ordered that the soldiers be fed with honey every day—a ration which at once revived their spirits, and strengthened and warmed

their bodies. In ancient times it was regarded as almost sacred, being the best food, medicine and drink, when prepared, to be found upon the earth. In Abyssinia, Russia, India, Palestine and other countries, refreshing drinks are made from it. In ancient Egypt it was valued as an embalming material, and in the East for the preservation of fruits and the making of cakes. In India a mixture of honey and milk is a respectful offering to a guest, or to a bridegroom upon his arrival at the door of the home of his bride's father.

Bees are also a benefit to every farmer and horticulturist wherever kept, as their value in fertilizing blossoms of fruit and clover can not be estimated. Our occupation brings us in contact with one of God's best gifts to man, and opens up a field for labor as flattering as any other where the same amount of capital is invested. Yes, more than this, it offers a source of making a living, and support to the sick, that no other occupation does. The labor and work is of such a fascinating character that it at once becomes a medicine and tonic to the weak and sick, and many have found health and success in following it when everything else had failed. As a combination with fruit-growing it can not be excelled. In fact, every one who lives in a locality where there is plenty of bee-pasture should keep bees if the locality is not already overstocked. There is nothing that will pay better, and bring such rich returns to the health of the family.

My friends, it has been nine years since I was first elected president of this society, and the time has come when I must leave you as such, and another must take my place. Whoever it may be it should be one who has plenty of time to devote to the interests of the society, and who is able to spend a little money. The society can only be kept up and in the front ranks by those whose work is a labor of love in its behalf. This and kindred societies can only be kept in the advance guard by the personal devotion of those whose hearts love the society and the calling it represents. The meetings which we have held during all these years have been pleasant and profitable to me. I have regarded you all as my friends; I have tried to do my duty, and have found you all ready to assist me; and I shall be pleased at all times in the future to hear of your happiness and prosperity. If there is ever a time when I can be of any service to any of you in any capacity it will make me happy to serve you, and I shall also be happy to hear from each one of you personally at all times. It is my wish that success and happiness may follow each one of you always.

J. P. WEST.

The address was well received, sympathy expressed for the president in his illness, and regret that he was unable to attend the meeting. The secretary was instructed to express the warm sentiment of the Association toward him.

The proposition to join the National Bee-Keepers' Association in a body was brought up and discussed. Owing to changes which would have to be made in the constitution if this were done, it was decided to postpone action until the next meeting.

Mr. Longfellow, a Minneapolis commission man, next gave a talk on shipping and selling honey. He said the best packages to use in this market for extracted honey are the 10-pound and the 60-pound tin cans; and for comb honey, 12 and 16 section cases.

Continued next week.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

LOAD A WORKER-BEE CAN CARRY.

Your editorial note on page 286 assumes that Astor's bees carried more of honey than of nectar because they could carry more. That may be it. A vat completely full of honey is heavier than the same vat filled with nectar; but I think we may wisely suspend judgment a little. Certainly the theory ceases to work if we try to account for the rest of Astor's figures that way. If bee-loads are 50 mg. (say June 15) and 25 mg. (say July 15) it won't do to say that on the earlier date the nectar was twice as heavy. The figures referred to have the appearance of having been selected or doctored in some way; but they are probably true in a general way. A bee securing a load all in one place may be expected to take about what it can. If the load is secured at a hundred different places, with as many flights between, we

may expect the bee to realize that the weight is tiresome and go home quite a bit before the limit of what it can carry is reached. Still more so when a thousand or several thousand flights must be made. Apparently this consideration ceases to govern after awhile; and the bee comes home occasionally (say each two hours or so) with whatever it may happen to have. To teach that there is a steady and regular decline of the amount of honey in the flowers with the advance of the season, would manifestly be incorrect; but, with a great many ups and downs, the general trend is that way, probably.

HOLDING QUEENS AND CELLS BETWEEN THE LIPS.

Doubtless perfectly dry lips will do no harm either to a queen or to a cell. It should be kept in mind, however, that the human saliva is a poisonous fluid (greatly *variable* in the degree of its poison) and we don't want our queens soaked in poisonous fluid, as bunglers would do it, should you tell them to hold queens that way. Even for delicate plants and seeds the mouth is a good place to keep them out of. Try it on nails, which can give and take in the matter of dirtiness and poison. If a high and refined degree of dirtiness is desired, with a spice of danger thrown in, try nickels and pennies. Page 286.

AN APIARIAN ROBINSON CRUSOE.

Mr. H. T. Hanna, we shall have to compliment you as an apiarian Robinson Crusoe, if you have a good location and no other apiary for eight miles. Page 285.

THAT BEE-KEEPERS' CLUB FOR QUEEN-REARING.

To have 100 bee-keepers club together and employ an expert queen-rearer at fair wages to rear 50 for each, is a decidedly new departure. Certainly there are some very manifest advantages and savings about it. Sure market in the place of a glut of uncalled for queens. Reasonable in the place of unreasonable dates. Fair lot and turn and "divy" in the place of clamor—or would the order of precedence be a specially hard thing to adjust without ill-feeling? There are also some weak points. I think I would rather collect my wages from one man than from a hundred. And, while the enlisting of half a dozen in the new scheme might be very easy, the life and drum might be pretty well worn out before man No. 100 "swore in." Page 291.

FIRE AT LONG-TONGUED QUEENS.

I'm right glad Mr. Doolittle fired himself off as he did on page 293. Little guns are excellent for many uses; but when an enemy develops that needs (badly needs) to be intimidated somewhat, then the heaviest gun in the service is just the piece to turn loose. Exactly how much good will come of the cultivating of long tongues *by measure* we don't know just yet. Quite a bit I hope (notwithstanding the "bang"), but it's plain to be seen that inaccuracy, and pretense, and conjectures that hardly amount to more than pretense, were going to get thick as the smoke of the pit. Long-tongued bees were going to mean just about as much as "pure white ead," or "pure baking-powder," or "pure gum drops," mean where no officer looks after frauds. Attention, ye buyers! When you get your long-tongued queens, get them with the same circumspection that you get the pure lead to paint your house. Testing the actual reach of bees at work is not so hard as to be beyond the reach of the ordinary apiarist; and 'speets it will have to come to that. Mr. D. pushes things too far in claiming that long tongues are of no profit except in red clover regions. Many long-tubed flowers have something to do with furnishing the total of nectar supply.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

THE TOBACCO HABIT.

Over 100 of our college folks—almost half of us—went to Los Angeles last Saturday to attend the Intercollegiate Oratorical Contest, and the second contest of three arranged with one of the colleges to decide who were champions in base-ball. I was proud, as our fellows won the trophies in the ball game, as they had won in the first, with a great score of 15 to 2. I was still more proud as we achieved victory in the oratorical contest. But I was most proud of the gentlemanly character of our students. One way this was

shown, was in the entire absence of smoking among our fellows. The others smoked. We did not. I rejoice that we have no smoking at our college. I wish tobacco was eschewed in all our homes. Our friend, A. I. Root, in "Our Homes," has done splendid service in urging against this habit. I wish I could be like happy in these "Home Circle" columns. To the hundreds of students that I have taught physiology, I have always spoken, as best I might, against all use of tobacco.

Boys and girls—and I rightly include girls—may I not have your ears a little to talk tobacco? We all wish to be sweet and clean. The tobacco user is usually neither. We do not wish to be offensive—a nuisance—to the most sensitive lady with whom we may seek or find companionship. The tobacco sot, certainly, the user of tobacco generally, is just that. We do not desire, certainly, to acquire a habit that will tend to dethrone health and court disease. Every wise physician will condemn tobacco as guilty of both these serious counts. Can we afford, in these days of keen competition in business, to strike at our chances of success? Several railroad companies no longer employ the cigarette smoker, and many employers will tolerate no one as an employee who uses tobacco at all.

The money spent for tobacco—though to my mind the least weighty argument against its use—should be thought of. The sum is enormous. If saved, how quickly it would pay all debts. How well it would clothe our people. How generously it would "bread and butter" us all. I would I might say the blessed word that would stay this frightful expenditure.

The worst count that perhaps can be brought against this arch enemy of the well-being of our people, and especially of our youth, is the tendency of the habit to make its patrons thoughtless—regardless of the comfort of others, and thus to destroy the gentlemanly instinct among us. How often in public places our ladies must endure the poisonous fumes from cigar or pipe. Only a few days ago I was presiding at a large picnic gathering, where speaking was going on, when some ladies appealed to me to relieve them from just such an annoyance. I have had to do this unpleasant duty over and over again. Can people acquire the tobacco habit, and preserve their gentlemanly instinct, all unimpaired?

There is a very serious side to this question—that of heredity. If, as many of our best scientists insist, the taste, inclination, and diseased tissues consequent upon the use of "the weed," are all likely to be transmitted to the dear children, then how can any of us acquire—how can any of us persevere, in this, oh, so common habit? If, as seems proved, wives and children are seriously poisoned by simply breathing the emanations from fetid breath and befouled clothing, then, indeed, we have most eloquent appeal to do all we can to stay the evil. And so I say, girls as well as boys. God be praised that our girls are saved from this danger.

But the girls have a proud privilege. They can influence against the habit that will tend so greatly to impair their happiness and well-being. God help all our girls to say boldly. "Yes, the cigar is offensive to me." For surely it must be offensive, morally at least, to every right-minded girl.

THE BOYS.

I read a pathetic account yesterday of a boy, just at that awkward age of 13, who was the victim of neglect and ridicule of his sisters. Home, that should attract, almost drove him away. One of the sisters heard a lecture on "Treatment of brothers." The words smote her to the quick. She went home, surprised her brother by the request to tie his necktie, and soon more by a present of a beautiful one. Within a day or two the big, awkward boy found his room neatly fixed with some pictures and other dainty attractions, which only the deft hand of girls can fashion. Wasn't the sister paid when the great boy threw his arms about her, and blubbered out, "Oh, but it's good to have a sister care for you!"

We would all like to practice one kind of theft. We would all like to rob the slums, the saloons, the street corners, and all other questionable resorts, where the dear boys are led to the bad. Loving attention at home, the words of kindly sympathy, the neatly fixed room, loving interest in game or any plan that is dear to the boy, will almost always result in this blessed robbery. The sister almost more than mother can be the proud agent in this worthy work. From 12 to 15 is the rapidly growing, awkward, blundering, bashful age with the boy. This is the time of sunshine. Let all in the home circle unite in the effort to make the boy, that it may be a good crop.

QUEENS!

Improved Golden and Leather-colored Italians and what H. C. QUIRIN rears.

We have one of Root's best long-tongued Red-Clover Breeders from their \$200 queen, and a Golden Breeder from Doolittle, who says if there is a **BREEDER** of golden bees in the U. S. worth \$100, this one is worth that sum. The above breeders have been added to our already improved strain of queens for the coming season. J. H. Eady, of Hamoldt, Neb., wrote us on Aug. 5th, 1900, saying that the colony having one of our queens had already stored over 400 pounds of honey, mostly comb; he states that he is certain that our bees work on Red Clover, as they were the only kind in his locality and apiary.

A. L. Root's folks say that our queens are excellent, while the editor of the American Bee Journal tells us that he has good reports from our queens from time to time. We have files upon files of unsolicited testimonials.

After considering the above evidence, need you wonder why our orders have increased each year? Give us a trial order and be pleased. We have years of experience in mailing and rearing queens. Safe delivery will be guaranteed, and instructions for introducing sent with each lot of queens.

QUEENS NOW READY TO MAIL.

Prices below July 1st:

	6	12
Warranted stock,	\$.75	\$ 4.25

Bees Wintered Fairly Well.

I could not get along without the Bee Journal. My bees wintered fairly well last winter, and they are in good condition. I now have 14 colonies. I commenced three years ago, but lost the most of them the first two winters. I tried to keep them in an out-house, but it was too cold. Last winter I had them in the cellar under the house, and they did well, and came out very strong this spring.

This country is very good for bees. There are lots of all kinds of flowers, and white clover that blossoms all summer. My bees carried in pollen the last of March, but it is quite cold in the winter, and the bees must have a good cellar, when they will do well here. I have had two swarms of bees this spring.

This was written by my son, Winfred Schmidt. I gave him a swarm of bees to start on, and he is going to be a bee-keeper when he gets bigger. F. C. SCHMIDT.
Price Co., Wis., May 27.

Bees in a Hemlock Tree.

I was in the woods all winter, and the first tree that I cut down was a very large hemlock, out of which I got a colony of bees. They were in a hollow 62 feet from the ground. I cut out the wood around the bees, making a block about 3 feet long, which I rolled onto the sleigh, and took home. W. E. YOCUM, Ontario, Canada, May 29.

Honey as Food and Medicine.

I agree with Mr. Doolittle about honey being good for both food and medicine. We eat it the year around, and have no sickness to speak of. It is so good for children, curing colds, sore throat, and almost everything that a child is subject to. We eat an average of a pound and a half a day.

Our honey crop was very poor last year. Jefferson Co., Colo. Mrs. F. B. SEBERT.

A Report from Tennessee.

I caught a swarm of bees a few years ago, subscribed for the "Old Reliable," became interested, and now have 10 strong colonies and one new swarm. I have bought about a dozen queens, but don't have very good luck with them, so we still have blacks and hybrids. I do not expect, nor desire, many swarms this spring, but have nine new hives awaiting occupancy. I use the S-frame Simplicity, and plain sections and frames. I don't think there is any money in bees in this section, but there is much pleasurable pastime.

White clover is abundant, and has been in bloom for two weeks. Bees are busy, but have not done much work in the sections yet. R. H. FIBER KLAND.

Perry Co., Tenn., May 18.

From Wisconsin to Washington.

Bees did not winter very well in this locality as a general thing; some bee-keepers lost quite heavily while others did not lose any. The spring has been very favorable for them to build up, and the prospect is for a good honey-year. The weather has been very warm, and somewhat dry, but lately we have had plenty of rain.

On the morning of May 16 I left home for the Pacific coast, going by way of St. Paul, passing through a portion of northern Wisconsin, across Minnesota, North Dakota, Montana, a portion of Idaho, and into central Washington—a jaunt of nearly 4000 miles—and I did not see a single bee-hive, although I was on the lookout for bees. While in Lincoln County, central Washington, I heard of a man 15 miles away that had some bees. I

did intend to make him a visit, but did not have the time. He was on the Columbia River, and in the midst of a fruit-growing region.

I did not see any alfalfa growing, though in some sections of Washington it is grown quite extensively. Brown-grass is beginning to be sown in central Washington, but clovers do not seem to grow. There is no irrigating done in Lincoln and Douglas Counties. These counties are in the famous wheat-growing region known as the Big Bend country.

No person, I care not how good he may be with a pen, can give an adequate idea of this wonderful country. It must be seen in order to be appreciated.

I intend to make Washington my future home, and have purchased 230 acres of land all under the plow, part of it in wheat, a house and barn with outbuildings, and an orchard, for the consideration of \$14 per acre. I do not intend to part with my old and tried friend, the American Bee Journal, though some ties must be severed and friendly associations broken.

L. ALLEN.
Clark Co., Wis., May 3.

Of the Waterleaf Family.

I enclose a plant that is getting into the fields here. What is it? JOHN M. SEILER, Hennepin Co., Minn.

[The plant in question is *Ellisia Nyelela*, and belongs to the Waterleaf family. It is quite common in more southern States, and is probably enlarging its borders by taking in choice sections of Minnesota. I do not know whether or not it furnishes food for bees. Watch it.—C. L. WALTON.]

Heavy Locust Bloom in Kentucky.

The prospects for a good honey crop here are not as good as I wish they were, but perhaps everything will come around all right yet. We have had an unusually cool, gloomy spring, and everything is from 15 to 25 days late. White clover is beginning to bloom, and we are having the heaviest locust bloom I ever saw, but the weather is so bad that the bees work on it but little. W. S. FEEBACK, Nicholas Co., Ky., May 29.

A Beginner's Report.

I have 9 colonies of bees, and one of them swarmed April 27. They wintered on the summer stands without loss. They are storing in the supers now.

Prospects are good in this locality. The hillsides are white with locust bloom, and fields are covered with white clover.

I am a beginner 16 years old, and love my bees and bee-papers. R. W. SMITH, Botetourt Co., Va., May 27.

Bees in Fine Condition.

Bees are building up nicely at present. The early spring was too cool for them to do much on maple and willow, but they have done unusually well on fruit-bloom, and are getting in fine condition for the white clover harvest, which, from present appearances, will be good. L. JONES, Floyd Co., Iowa, May 29.

Queen Visiting a Deserted Hive.

While going through my hives on May 16 I found one deserted, and moved it out of the bee-yard, back of my implement house, about 100 feet from where it had been. I was taking out the combs, and hunting and destroying the moth-worms that had a start in them, and while at work a black queen lit on one of the combs. I tried to catch her, but she circled around and lit on the side of the house, when I caught and caged her. I then examined the rest of my colonies, but could find none without a queen. Where do you think she came from? and is it not very rare for one to be around here that late?

The past winter was very hard on my bees. They were flying almost every day, and used

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2; or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

up all their stores, and I have lost 13 colonies through spring dwindling, and expect to lose more. I have been feeding, but the bees are not there to build up.

I think there is no better country in the United States for all purposes than the Cherokee Nation country. R. N. CRAFTON, Cherokee Nation, Ind. Ter., May 18.

The Weather Hard on Bees.

My bees were in splendid condition in March, breeding up strong, and they worked three days on maple blossoms, the trees having the finest amount of bloom on them that I ever remember seeing, the blossoms being as large as peach-blossoms. But suddenly it turned cold, and thousands of the poor little bees were caught napping, they could not get to their hives, and perished. The frost killed all of the bloom that was far enough advanced to be affected, and all through the greater part of April we had cold rains and frosty weather, then there was a great profusion of fruit-bloom; but the bees did not seem to be strong enough to take advantage of it, and in the midst of it came a heavy, cold rain and hail-storm which destroyed the bloom.

The bees have had a hard time of it, though most of them are in good condition now. Some are weak, but most of them are clustered at the entrance waiting for white clover, which is looking first-rate, and there are a few blossoms here and there.

We have had no swarms so far this year.

D. C. McLEOD, Christian Co., Ill., May 27.

Bees Starved in Iowa.

A good many of the bees in this part of the country starved last winter. I have 30 colonies in good condition, and increasing fast.

I clip all queens, cut out queen-cells, give plenty of room—two or three supers at once—and have very little swarming. I sell all my honey in the home market, and stamp every section.

GEORGE C. DEBBE, Jasper Co., Iowa, May 30.

Bees and Olives.

These are suggested by W. A. H. Gilstrap in the Bee-Keepers' Review, as a desirable combination. He says:

The bulk of the work with olives is done between Oct. 1 and March 1, then for three months the work is moderate with both bees and olives. Some time in June or July the honey harvest commences and lasts until Oct. 1, when the fruit is about ripe. By that plan one man can put in his time the year through in one place, having no idle spell. Perhaps that would be more profitable than any other method in some cases, while in other surroundings, with other men, it would not.

Smothering a Colony of Bees.

This is a much easier thing than the novice would suppose. Nearly every one must suffer a personal loss in order to learn the lesson. Possibly some may be induced to be careful without any personal experience by reading the following case reported by Dr. C. S. Phillips, in the Southland Queen:

I want to tell you how we lost a large, fine swarm. There was a swarm that came out and my wife hived them, and they came out and went back. They did this two or three times, and the last time was on Saturday, and when I came home from the office she told me of it. I said, "All right; I'll fix 'em. Sunday they will not come out."

So Sunday morning I got some wire-cloth and fitted it over the entrance to keep them

in, and said, "Now I've got you," and went on to Sunday-school and church content. When I returned I went to see our bees, and noticed that the ground in front of the hive was wet, and the bees looked lifeless. I opened the hive, and they were all dead. They had smothered to death. What a fine swarm lost, for they had in 13 hours built the eight frames of foundation half full.

Giving Combs of Honey to Swarms.

Editor Hutchinson says in the Bee-Keepers' Review:

Combs of solid honey may be placed in the brood-nest when living swarms, and the honey brought in will of necessity be carried into the sections. Friedländer (Greiner mentioned in one of the New York institutes, saying that he had frequently practiced the plan, and in addition to being compelled to put the new honey above, the bees are also obliged to remove much of the honey from the combs put in the brood-nest, and carry it up into the sections, in order to make room for a brood-nest. This management is not only the honey-brought-in honey put into the sections, but any combs of first-class honey may be "worked over," so to speak, into section honey.

Queen Accepting Bees.

Editor Pender says in the Australasian Bee-KEEPER:

During a honey-flow bees are so much engaged as hardly to notice a change of queen, provided the queen does not disturb the bees herself. I have had bees too busy gathering even to start cells when made queenless. During a scarcity of honey queen-introduction is not at all certain. The bees are idle and resent interference. The editor of Gleasons does not understand how fastening for 30 minutes on the part of the queen should induce a friendly behavior on the part of the bees. In queen-introduction I find success is due quite as much, if not more, to the disposition of the queen. I never introduce a queen if she is excited, and runs about madly in the cage. I simply withdraw the candy and starve her until she is prepared to beg for food, and thus PREPARE HER to accept of the bees. We usually prepare bees to accept of a queen. Cause a queen to run excitedly over the combs and the bees will ball her at once, even their own queen, how much more a stranger.

Bees of a Swarm Living Longer.

Knowing what a short lease of life worker-bees have in the busy season, it seems a little strange that the bees of a swarm hold out as well as they do. In the British Bee Journal H. B. Buckton reports some experiments concerning the matter, and concludes by saying:

The reason, then, why bees in a swarm live longer than usual seems to be that the younger bees of the swarm have to serve as indoor workers for a longer time than they would do in a hive containing constantly-hatching brood, and they thus are not exposed to the accidents and hard labor experienced by field-workers.

Shall Hives Be Painted?

In defense of painted hives, A. C. Miller says in the Bee-Keepers' Review:

An unpainted board will absorb moisture freely; coat it with paint or varnish and it will not. When it is thus coated the outside cellular structure is a fair non-conductor; hence, a hive coated with varnish on the inside and paint on the outside, is, in limited way, the same as a chaff hive, i. e., a porous poor conductor between two better conductors. When the pores in the wood of a single-walled hive are filled with water, which is a good conductor, the hive becomes a little better than if it were made of metal or stone.

After 28 Years. We are not much in sympathy with advertisers who make use of extravagant claims as being "biggest," the "best on earth," "none so good," etc. When, however, these or similar claims are borne out by the actual facts we believe that the advertiser has not only a perfect right, but that he should make the facts public. This is brought to mind by the advertisement of the Elkhart Carriage and Harness Manufacturing Co., of Elkhart, Ind., who regularly use this paper in season. These people for the past several years have been laying claim to being "the largest manufacturers of vehicles and harness in the world selling to the consumer exclusively." To one who will take the pains to investigate, or what is better still, if it is possible, go to Elkhart and look over this institution and examine their methods of doing business, this statement will appear as the truth. Of course this result is not one of sudden attainment; it has taken more than 28 years of hard and persistent effort to bring this institution up to its present high plane. Having de-

(No. 272 Open Driving Wagon.)

cided long ago that the public would much prefer to deal direct with the manufacturer, the man who made the goods, if the people but could be convinced that they were getting the best goods at the lowest procurable price, the Elkhart people inaugurated their present system of doing business. That their methods have been approved and appreciated is evidenced by the growth, magnitude and prestige of their present business. In their two large factories at Elkhart they manufacture 178 styles of vehicles and 63 styles of harness. In vehicles they are prepared to supply the public with every conceivable article from the open buggy through phaetons, stanbopes, a long line of top-bucies, surreys, two and three seated carriages, traps, spring-wagons, etc.—to wagonettes, busses and all classes of delivery wagons. In harness they have anything from single-strap buggy-harness all down the line to best double-team harness for farm work. Remember that they make every article they sell in their own factories, and that they employ no agents or middle men, but sell exclusively to the consumer at wholesale prices. Every article is guaranteed in a way that removes all element of chance. Everything is made of good material in the most substantial way, in the best and latest style, and sold to the consumer at the most reasonable of prices. Write them for their large illustrated catalog which they will take pleasure in sending to our readers. Do not forget to mention seeing their advertisement in the American Bee Journal.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 7.—Not any new comb honey has come to this market up to date heretofore, but promises are being made for some before the month closes. A little good white comb still on sale, which easily brings 16c; not much of any other kind here. Extracted very dull, practically no sales made. Beeswax fair at 30c. R. A. BURNETT & CO.

DETROIT, May 21.—Fancy white comb 14@15c; No. 1, 13@14c; dark and amber, 10@12c. Extracted, white, 1/4@7c; amber and dark, 5@6c. Beeswax, 27@28c.

Very little desirable honey in sight. The new crop will find the market well cleaned up. The demand is always light at this season of the year. M. H. HUNT & SON.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull, and more or less forced; lower prices from 1/2 to 1 cent per pound. C. H. W. WEBER.

BOSTON, May 21.—Our market continues dull on honey with very light stocks on hand. Our normal prices are as follows: Fancy 1-pound cartons, 17c; No. 1, 16c; No. 1, 15c; No. 2, 12@14c. Extracted from 6@7 3/4c. BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00. PEYCKE BROS.

NEW YORK, June 1.—Extracted honey is exceedingly dull and very little moving. We quote for the present: White, 6@7c; light amber, 5 1/2@6c; amber, 5@5 1/2c. Some demand for comb honey at unchanged prices. New crop is now beginning to arrive from the South, and sells at from 12@15c, according to quality and style. Beeswax, 27c. HILDRETH & SEIGLER.

ALBANY, N. Y., June 1.—Honey market quiet. No stock, no receipts, and no demand now. It is between seasons. We look for good prices the coming season, for in this vicinity the foot brood has nearly exterminated the bees. H. R. WRIGHT.

BUFFALO, May 29.—Very light trade in all grades of honey. Strictly fancy sells fairly, at 14@15c; dark dull at any price, and 8@9c about the range. Beeswax, fancy, 27@28c; dark, 23@25c. BATTERSON & CO.

KANSAS CITY, May 4.—Practically no shipments arriving, and very little selling. We are getting \$3.50 to \$3.75 per case of 24 sections No. 1 white; amber, \$3.00 to \$3.25. Beeswax scarce at 25c. W. R. CROMWELL PRODUCE CO., Successors to C. C. Clemons & Co.

SAN FRANCISCO, May 22.—White comb 11 1/4@12 1/2 cts.; amber, 10@11c; dark, 6@6 1/2 cts. Extracted, white, 5@6c; light amber, 4@4 1/2c; amber, 3 1/2@4c. Beeswax, 26@28c.

Market presents a weak tone, with dealers, large and small, holding off as much as possible, in anticipation of liberal offerings from producing sections at an early day. There is not much new honey now here, either comb or extracted. For some very choice white comb 13 cents is asked. New amber and dark has been placed at 4 cents, which is the utmost figure obtainable in a wholesale way in the local market for this grade.

Illinois Day

at the Pan American Exposition.

Tuesday, June 25, 1901, has been selected by the Governor of Illinois, as "Illinois Day," at the Pan-American Exposition at Buffalo. In order to make that occasion a greater success, the Nickel Plate Road will lend its assistance by making the following rates:

\$13.00 for tickets good 10 days.

\$16.00 for tickets good 15 days.

\$21.00 for tickets good 30 days.

Tickets at above special rates will be available on any of our three through daily express trains from Chicago at 10:35 a.m., 2:30 p.m., and 10:30 p.m., which carry through vestibuled Pullman sleeping-cars and afford excellent dining-car service, on the individual club meal plan, ranging in price from 35 cents to \$1.00.

For further information and illustrated descriptive folder of the Pan-American Exposition grounds, write John Y. Calahan, General Agent, 111 Adams St., Chicago. 13—24A2t

I ARISE

To say to the readers of
the BEE JOURNAL that

DOOLITTLE...

has concluded to sell
QUEENS in their season
during 1901, at the fol-
lowing prices:

1 Untested Queen \$1.00

3 Untested Queens..... 2.25

1 Tested Queen 1.25

3 Tested Queens..... 3.00

1 Select tested queen 1.50

3 " " Queens 4.00

Select Tested Queen,

last year's rearing 2.50

Extra selected breed-
ing, the very best...\$5.00

Circular free, giving particulars regarding each class of Queens, conditions, etc. Address,

G. M. DOOLITTLE,

11A26t Borodino, Onondaga Co., N. Y.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

Note.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown here-with is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 5 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

MR. F. GREINER, of Ontario, Co., N. Y., writing us June 9, had this to say:

"The season so far has been exceptionally unfavorable. However, we take it stoically, as we look for a yield only from buckwheat later."

DR. JAS. McLEAN, whose interesting article on "Medicinal and Nourishing Properties of Honey" appeared on page 324, writes us that a slight error occurred therein, referring to the indigestion formulae regarding the quantity of honey, which should be one teaspoonful instead of one tablespoonful. He thinks it might be well to rearrange the whole sentence as follows:

"One teaspoonful of pure honey dissolved in a glass of cold or tepid water, into which mix one teaspoonful of tincture of myrrh, to drink shortly after eating."

MR. THADDEUS SMITH, whose picture is shown on page 389 this week, is a retired bee-keeper, though he has from 10 to a dozen colonies. He begins in this week's number, a series of reminiscences articles which we have no doubt will be read with much interest by all. He is between 70 and 80 years old, though no one would believe it if compelled to judge from the picture alone. It must be that the Pelee Island climate, in connection with a luscious fruit diet, contributes to longevity; and very likely honey also plays an important part in helping to keep him so young in appearance.

MR. J. M. RANKIN, as previously announced, is the recently appointed inspector of apiculture for the State of Michigan. We are pleased to present so good a likeness of him as on our first page this week. He is 26 years of age. He began bee-keeping at the age of 12, with two colonies, one in a Simplicity hive and one in a box-hive. During his first experience he made the acquaintance of a German bee-keeper by the name of Andrew Hunt, to whom he is indebted for careful and interesting teaching, and for a great deal of his early training in bee-culture.

When 18 years of age Mr. Rankin met foul brood for the first time, and it resulted in the loss of half of his 40 colonies, but the disease was finally stamped out.

He took charge of the experiment station apary at the Agricultural College of Michigan in April, 1897, and during the past four years has been a student there. He has done some good work with foul brood, and has gone several times to different parts of the State to assist bee-keepers in treating their apiculture to rid them of foul brood, so the work is not entirely new to him.

We had the pleasure of meeting Mr. Rankin at the Chicago convention of the National Bee-Keepers' Association last August. We feel that Michigan has made no mistake in appointing him to so important a position in the interest of bee-keeping. He will not disappoint those who labored so hard to secure the foul brood law, and who also recommended his appointment. On account of his investigating turn of mind, and decided interest in the subject, we bespeak for Mr. Rankin an honorable career in the bee-keeping line.

The Bee-Keeper's Guide;

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th 1899 Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without *The Bee-Keepers' Guide*.

This 10th and latest edition of Prof. Cook's magnificent book of 406 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal, with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let every body try it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

FREE as a ... Premium

A Foster Stylographic PEN...

This pen consists of a **hard rubber** holder, tapering to a **round point**, and writes as smoothly as a lead-pencil. The **point and needle** of the pen are made of **platinum**, alloyed with **iridium**—substances of great durability which are not affected by the action of any kind of ink.

They hold sufficient ink to write 10,000 words, and **do not leak or blot**.

As they make a line of **uniform width**, as you wish they are **unequaled for ruling purposes**.

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

BEST MANUFACTURING PEN ON THE MARKET.

13,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the "Foster." You should have one also.

How to Get a "Foster" FREE.

Send TWO NEW SUBSCRIBERS to the American Bee Journal for one year, with \$2.00; or send \$2.00 for the Pen and your own subscription to the American Bee Journal for one year; or, for \$1.25 we will mail the pen alone. Address,

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., JUNE 20, 1901.

No. 25.

* Editorial. *

The Season seems to be unusually unfavorable. Cold and dry weather has prevailed over a large area, while some portions complain that it has been too wet. There is some complaint that white clover is plentiful, but that the bees get little or nothing from it. Unless very close watch is kept, there is danger that some colonies will be starving in June.

Starting Bees in Sections.—Mrs. Barber and others are warm in praise of the plan of giving bees an extracting-super to start them to work, and a day or two later replacing the extracting-super with a super of sections. Referring to this, M. A. Gill says in *Gleanings in Bee-Culture*:

In advising the use of an extracting-super to start to work in sections, are you not aware that thousands of us bee-keepers do not have an extracting-super on the place? I would advise any bee-keeper working for comb honey to exchange supers with colonies that are tardy about working in sections with one that has made a *good start*, and be sure to carry along some of the comb-builders (young bees) which are the last to leave the super. The colony given the super with full sheets of foundation will at once resume work, from the force of the same habit you say they have acquired by the use of your extracting-super.

A Satisfactory Hive-Cover—at least one that is satisfactory in all climates—is hardly yet on the market. Editor Root says that the perfect hive-cover is yet to be made for Colorado, Cuba, and other countries that are different from the northern part of the United States. He hardly need to have made any distinction, for objections against a cover in Colorado would still lie against it in New York, only in less degree. Possibly one trouble in the case has been that there has been too strong a feeling that the expense of a cover must not much exceed the cost of a plain board. Something must not be expected for nothing, and a good cover being so essential a part of a hive, the wise bee-keeper will hardly object to some extra expense. Perhaps it would be a good idea to have a pretty thorough discussion as to the points of a good hive-cover. Some of them may be as follows:

Lightness: a cover must be lifted a good many times, and it makes a big difference whether it weighs five pounds or twenty-five.

A freedom from warping and twisting: a plain board cover may be firmly cleated at the

ends that it can not possibly warp, but the cleats can not in the slightest degree prevent it from twisting so it will not lie flat on the hive.

A dead-air space: this will make it cooler for summer and warmer for winter. To be sure, a shade-board can be put over in summer, and something of the same kind may be effective for winter, but it is more convenient and satisfactory if cover and shade-board can be all in one.

A hive-cover with these requisites would make a perfectly close fit, and, if made perfectly rain-proof, ought to give pretty good satisfaction. In spite of the expense, some have covers covered with tin, so as to make a sure thing against leakage. Lately Neponset roofing-paper is mentioned as a close competitor of tin. *Gleanings in Bee-Culture* reports it still doing good service after 12 years' use. Of course, it must be painted; but so must tin.

Improvement of Stock is in the air nowadays. Unfortunately it is "in the air" in too literal a sense. There is a general reaching out after it, and a feeling that somewhere in the air about us there is something like improvement if we only knew enough to get hold of it. We are just now getting along so far in the matter as to begin to realize that we know nothing about it. The editor of the *Rocky Mountain Bee Journal* says:

"Who among us will deny that darkness, black as Egyptian night, envelops the whole bee-keeping world on this subject? This includes queen-breeders, bee-journal editors, and all others."

Well, it is a hopeful sign when one begins to feel his ignorance, and the reaching out after light gives promise of good things to come. If control of mating becomes an established fact, why should there not be just as intelligent work done in breeding bees as in breeding any other class of stock? Even without control of mating, if enough interest can be aroused to get all the bee-keepers to breed only from the best, there will be a great gain.

Sections Filled with Foundation have an argument in their favor sometimes not thought of. If you are wise, you will probably have in the brood-chamber much less drone-comb than the bees desire. It is the natural thing for them to fill out largely with drone-comb for storing, and the two kinds of comb do not look so well in a section. You probably have thought of that, but that is not all. The bees desire drone-brood, and if you keep careful watch you will find that sometimes as much as half or quarter of the section has not a drop of

honey in it when sealing is well along in the super, because the bees are holding these cells open for the queen to lay in. If the section is filled with worker foundation, then there is no chance for drone-comb there. Those who use full sheets of foundation in sections do not find it necessary to use excluders to keep the queen down.

Size of Entrance.—Editor Doolittle says in the *Progressive Bee-Keeper* that he regulates the entrance to suit the size of the colony. After the first flight in the spring he allows to the strongest colonies an entrance of $2\frac{3}{4}$ inches, and from there down to $1\frac{1}{2}$ inches for the weakest, leaving them thus during early spring. When the bees begin to work on early pasturage, the entrances are enlarged as needed to allow free passage.

Box-Hives and Skeps in other countries seem to be more common than in this. A writer in the *British Bee Journal* says: "I can get as many driven bees as I like for the trouble of 'driving.'" The writer says he makes his hives out of used boxes, and he has taken the first prize for the best hive made by an amateur. Most bee-keepers on this side would hardly feel they could afford to make their own hives from common boxes.

Yellow Sweet Clover.—Successful crops of this clover from one sowing are reported in *Gleanings in Bee-Culture* by M. M. Baldrige, December 2, 1897, seeds were put in a shallow trench and covered with one or two inches of soil. From this sowing came three distinct crops, the last in 1899, which must all have come from the same sowing. He says it sometimes winter-kills, and, like the white variety, it is a biennial.

Getting Light Extracted Honey.—Mrs. Harrison tells in *Gleanings in Bee-Culture* about some extracted that she put on exhibition in competition with a number of other samples, and upon which she obtained a premium. Hers was distinctly whiter than the others, which did not at all differ from each other. Her competitors thought there must have been some trick about it, and she told them the trick. She extracted from none but pure-white combs. Holding the comb up to the light, if she saw a few cells of dark honey, those few cells were not uncaped. All utensils were clean and free from other honey. That was her "trick" for getting the whitest honey. This trick is a familiar one across the water, but bee-keepers on this side are hardly equal to their foreign cousins in getting up extracted honey for exhibition.

Convention Proceedings.

(Continued from page 378.)

Report of the Minnesota Bee-Keepers' Convention.

BY DR. L. D. LEONARD.

SECOND DAY—AFTERNOON SESSION.

Mr. Corbett, of the Dairy and Food Commission, talked of the work done by that Commission in the State. Of 150 samples of honey examined in two years, 25 percent has been found to be adulterated. Four dealers have been prosecuted for selling adulterated honey, and fined to the amount of \$50. The following letter in regard to the matter, was read:

Hon. J. P. WEST—

My Dear Sir:—Pursuant to your request to Major Bowler, I send you the following names of those who have been convicted and fined for selling adulterated honey this year:

Schnauss & Zeigler, Duluth, Feb. 23, 1900,	\$15
Ole A. Berg, " " March 12, "	15
Mallough & Son, " " " 15, "	15

The second named was fined for selling imitation honey.
Yours very truly,

MAY A. GRINDALL,

Stenographer Dairy and Food Commission.

Miss Moeser then gave a talk on cooking and canning with honey.

The advisability of having a Minnesota honey exhibit at the Pan-American Exposition, at Buffalo, was next discussed, and Dr. E. K. Jaques was appointed to take charge of the matter for the Association.

The following paper by G. H. Pond, was then read:

DISPOSING OF THE HONEY CROP TO THE BEST ADVANTAGE.

In considering this subject we must first decide whether we want to get the most for our honey regardless of the time required; or, is our time worth so much that it is best to sell our honey the easiest and quickest way? If we come to the latter decision the bee-keepers of Minnesota have an excellent outlet for their honey through the commission merchants of Minneapolis and St. Paul; and I think we can obtain better prices for our honey through them, than do those who ship to the large Eastern cities.

But perhaps most of us will decide that our time is not worth so much that we feel warranted in following this plan, and if by spending more time in disposing of our crop we can get a better price, we would better do so. Now I do not propose to advance a theory, but to give a few facts from experience, and as I have had no experience in producing or selling comb honey, I shall dwell only on disposing of extracted honey.

Honey is an article that people in general do not buy unless it is brought to their notice, so, in order to sell, it is necessary for us to put it up in a very attractive way, and then bring it to the notice of the people as much as possible. In peddling honey among farmers I have found that the oftener I go, the more I can sell; and this rule holds good wherever I have sold honey. "Keep going" is a good motto for any one who would sell honey.

A satisfied customer nearly always tells a friend or two, and shows them the honey, and in this way the business is extended, so that the more one sells the more he can sell.

I have learned by experience not to try to induce people to buy more honey than they wish at one time, because sometimes when they buy too much it candies, or gets in an untidy condition otherwise, and thus they get set against it. It is strange how many people there are (who ought to know better), who think that when honey candies it is spoiled. For example, I have supplied a certain hotel with honey for two or three years, and they take over 100 pounds at a time, getting it three or four times a year, and I supposed they knew how to care for candied honey. But this fall their kitchen-man told me that the last honey I brought them was not good, and on examining it I found that all that allied it was that it was candied. A new kitchen-man had been employed and he did not understand about it.

In selling honey put up in glass packages to retail grocers, I find that if the honey candies on their hands their sales of

it about come to a standstill. And although I tell them that heating will restore it to a liquid form, and they say that they will try it, I do not remember that a single one of them ever did. So I have found that the best way is for me to exchange it for honey freshly put up, and take the candied home and relinquin it myself.

To sum it up, then, the most important points in disposing of our honey crop to the best advantage are:

- 1st. Produce a first-class quality of honey.
- 2d. Put it up in as attractive form as possible.
- 3d. Bring it to the notice of customers constantly.
- 4th. Keep your customers satisfied. G. H. POND.

Next, a paper was read by Dr. Mary McCoy, on

BEE-KEEPING NEAR DULUTH.

Years ago I became interested in the bloom in and about Duluth, as a possible profitable field for the support of the honey-bee. The spring season of Duluth is always about three weeks later than that of the southern part of the State, our earliest bloom being the dandelion, which is an abundant producer of pollen and some very bitter honey that is claimed to be very stimulative. We have some fruit-bloom—apples, cherries and plums—but there are not enough trees, all told, to make a fair-sized orchard. I do not think that basswood is indigenous to the country about Duluth, and there are but very few trees planted in and about the city. Until the past summer buttercups have been very plentiful, and have always ushered in the white clover which formerly literally carpeted the whole surrounding country, as well as the vacant lots, squares and parks of this city. Wherever a fire sweeps the country Nature attempts to cover the charred and blackened foliage with a profusion of the fragrant white clover bloom, and as Duluth has only recently been reclaimed from a wilderness, and fire has been one of the reclaiming agents, it has had plenty of barren spaces to beautify.

There are a few other wild flowers, such as the wild strawberry, the wild cherry, and the wild rose, which all help very materially, and I could not help noticing how heavily the wild cherry-tree bore which grew near where the bees were placed.

In the early fall the fire-weed puts in an appearance and the honey stored from it is as fine as that from the white clover.

The weather is cool enough here so that the bees do not care to hang outside of the hive, and the first summer we kept them they did not loaf more than one or two days. The past summer was a little warmer, and they loafed a little in the middle of the day, but their loafing is not to be compared with what I have seen of it in the Michigan aparies.

We have had no experience with any bee-diseases in Duluth, and have had no spring dwindling. I do not think the bee-moth inhabits Duluth, or, if it does, perhaps the bees (like the people of our city) are too wide awake to let it get a foothold. Suffice it is to say that since the first summer that we purchased the bees we have discovered none of the moth-larvæ. We know nothing about foul brood; it is a disease that has not yet gotten into our part of the State. I don't think there ever has been any in this section, and I hope there never will be.

There are about 10 people in and about Duluth that keep bees. One family has kept them over 20 years. I asked the head of this family—she is a widow—if it paid, and she replied, "Well, I've paid off the mortgage on the farm, sent the children through high school, and one through business college, and built a kitchen on the house, and all I've had to do it with has been my 60 colonies of bees." So she has found it profitable.

We have been keeping bees for about four years, starting with two colonies. White clover began to blossom about May 15, the spring being unusually warm and early, and as we had plenty of rain throughout the summer, and the frost was late in appearing, our honey season lasted till September. That year we increased to six colonies, and secured 178 pounds of beautiful white clover comb honey, which was selling in Duluth at that time at 15 cents per pound. The next summer the yield was fair, but as the bees were five miles from our home they did not get the attention they should have had, although we increased to 12 colonies, and secured about 300 pounds of honey. We had scarcely any snow last winter [1899-1900], and the white clover was badly winter-killed, so much so that we thought for a while that we would have none at all; but if clover was scarce, the price of honey was high, so we did not do so badly, after all. We sold one colony to a friend, and with the honey which we sold and ate, we figured that our debit and credit sides have come out about even. We discouraged swarming all we could the past sum-

mer, doubling up any colonies that were weak, and have 24 colonies in winter quarters [Dec. 1, 1900].

We have kept our bees in the heart of the city for the past two years, but we will hardly dare to do so any longer, as they are getting too numerous, and, besides, I am afraid the grocers and candy manufacturers would not stand their onslaughts another season as well as they did the past one. A grocer informed me that he never knew so many bees to be shipped with fruit as was done this past year. I kept discreetly silent, as he laughed and told me of one of his customer's antics when she picked up a peach and squeezed a bee which had alighted upon it. By-and-by they found that we kept bees, within two blocks of the main street of the city, and then it was not so funny.

Of the 10 families in and around Duluth who keep bees, I think that all, with possibly two or three exceptions, have made it pay. The field is a good one so far as clover is concerned, but it is not so good in some other respects. The absence of fruit-bloom, the lateness of the spring seasons, the early frost and abundant rains, make prolonged feeding necessary, and this reduces the profits. But then the quality of the honey must be considered—none finer is produced. It is as white as the driven snow, and I believe Duluth stands at the head of the world for the whiteness and purity of its honey. The fireweed and the white clover, which are honey-plants par excellence, grow profusely. I feel certain that if I had the time to devote to the bees which I should like to have, I could clear at least 70 pounds per colony in a season. While the yield here may not be so great as in some other places, the superior quality of the honey and the greater price which it commands, make the industry enticing.

(DR.) MARY MCCOY.

QUESTION-BOX.

QUES.—What plant can be sown with good success for bee-pasturage?

The opinion of those present seemed to be in favor of sweet and alsike clovers.

QUES.—What is the cause of foam rising on extracted honey? ANS.—Uripe honey.

QUES.—For bees wintering in the cellar, are quilts under hive-covers an advantage? ANS.—Yes, as the quilt absorbs moisture.

QUES.—What is the best method of protecting extracting-combs from the bee-moth? ANS.—By fumigating with bisulphide of carbon, and freezing.

(Concluded next week.)

Contributed Articles.

No. 1.—Some Reminiscences of an Old Bee-Keeper.

BY THADDEUS SMITH.

I PROPOSE to give some recollections of the time, incidents, and persons, connected with bee-keeping over a quarter of a century ago, and some incidents of my own personal experience of 30 and 40 years ago, with notices of prominent cotemporary bee-keepers and the great changes and improvements made in the science of bee-keeping within my memory—the introduction of the movable-comb hive, and the Italian bee. This first article will be given to the writer's early experience and the condition of bee-keeping at that time, but in future numbers he hopes to be not quite so prominent a figure.

I was brought up on a farm in Woodford Co., Kentucky, ten miles from the city of Lexington, and as far back as my earliest recollection my father kept a number of hives of bees, and I became interested in them when quite young. The first hive of bees that I owned was about 60 years ago. In coming home from school one afternoon I found a swarm of bees clustered on a low elder-bush not far from our house. It was duly hived, and the colony always went in my name.

My father having but one hand I had to assist him with the bees when quite young. The management of bees in those days consisted mainly in caring for them in the common box-hive with a cap on it for the surplus honey, and removing this cap when it was full of honey; and no finer or better honey than that was, can now be obtained by the

most elaborate modern surplus arrangement, though we now get it in much better shape for market.

The wintering problem that now enters so largely into bee-management, did not seem to give us any concern in that climate. The hives all remained on their summer stands, without protection, all winter, and I don't remember any loss sustained, except some late swarm that was neglected to be "taken up" in the fall had starved to death.

The hives were large, and as no honey was ever taken from the interior, unless the bees were all sulphured, they usually had enough to winter on. The hive that was the first one that I called mine, already mentioned, was about 14-inches square, and the same in height, somewhat larger and of different proportions as to width and depth than those in general use. It was placed on the north side of a long building where the sun never shone upon it except a little while in the early morning, and according to my best recollection it remained there without change or renewal of bees for some eight or ten years. So there could not have been much trouble in wintering.

But there came a time, for a number of years, when the moth worm or miller became very bad indeed. Whole

MR. THADDEUS SMITH.

apiaries looked as if they would be destroyed by them. We did not know then, as we know now, that it is only the weak and queenless colonies that are destroyed by the moth. Such is undoubtedly a fact where movable-comb hives are used, and some assistance can be given the bees in getting rid of the moth, but it did seem, in those days, that some of the colonies would succumb to their attack.

It has been said that wherever there is a demand there will be a supply. So we soon had offered us patent moth-traps, and patent moth-proof and moth-catching bee-hives. Agents with models, beautifully made of mahogany or rosewood, perambulated the country. The worms, (perhaps Prof. Cook would say I ought not to call these things "worms"—I may learn after a while, but excuse me for the present), when matured or dislodged by the bees, would fall to the bottom-board and take refuge under the bottom edges of the hive, and under the combs that came near the bottom, and I had to go early every morning and tilt the hive back and kill the worms. This was a pretty good non-patented moth-trap, but required close attention and work, accompanied sometimes with bee-stings.

My father set about to devise a better plan to get rid of these worms that fell to the bottom-board, and to break up their hiding-place and prevent them getting up into the combs again. He had the hives all raised from the bottom-board by driving a big nail in each of the four corners, leaving them to project three-quarters of an inch, forming an entrance that high all around the hive. These he set

upon smooth flat stones, that were easily procurable, from one to two inches thick, and laid flat on the ground, distributed all about over a large yard. Now when the worms fell to the bottom they had no place to hide, could not get back on the combs, so had to go to the ground, and many were picked up by the chickens and birds—the little brown house-wrens were often seen busy around the hives gathering these worms for their brood.

My father tried other projects—had hives placed in a house, and had the entrance to them through long flat tubes extending a foot or so outside the walls of the house, so the moth-fly could not find her way into the hive, I suppose. He had a theory that it was necessary for the worms to have access to wood for material to form their cocoons with, as we often see them scrape and cut into the wood of the hive to enclose themselves; and he got the idea of having hives made like common crockery or stoneware, but not being near to any crockery manufactory he failed to try the experiment. The hives placed upon the stone with an open entrance all around that was never closed or contracted, winter or summer, seems to have given the best satisfaction, for they were used in that way until I adopted the Langstroth movable-comb hive in 1893.

I remember some curious devices of my neighbors' One had a hive suspended by chains in a tree some 20 or 25 feet from the ground—to imitate the natural abode of bees in hollow trees, I suppose. Another had a bee-house with arrangements for getting surplus honey from *below* the hive instead of the usual way from the top. A trough-like box 12 or 14 inches square extended around the inside of the house, and was divided into compartments, and upon this box the hives were set, the bees having to pass through the box to get out. When they had filled the hives, they would fill the box below, and a trap door was arranged on the box so the honey could be cut out. He claimed that it worked well.

There was another curious bee-house in his front yard. It was a section of a very large hollow sycamore tree, probably four feet in diameter and eight feet high. It was placed upon a post a foot above the ground with a floor in it, and a neat, conical roof of shingles, with a staff in the top, and was quite ornamental. A door was sawed out and was hinged so that one could go into it; and in it an ordinary box-hive of bees was placed. When the bees filled the box they would build comb all over and around the outside of it. The door to the big "gum" was opened, and the honey outside of the hive cut off whenever needed, or as cool weather came on. I don't know whether this colony ever swarmed or not.

Ontario, Canada.

Bee-Keepers' Exchanges—Organization and Co-operation.

Written for the Wisconsin State Bee-Keepers' Convention held at Madison.

BY C. A. HATCH.

WE have so often heard it said, "In union there is strength," that it has lost its power to affect our understanding. A single straw would not be much to match against a man's strength, and yet if that single straw be increased by numbers enough it can defy the strength of the strongest man.

An army would not accomplish much if each soldier were allowed to go and do as he pleased regardless of every other soldier; but it is only when the soldier ceases to be an individual, and becomes a unit of the whole, that it becomes an army and ceases to be a mob, that effective work can be done, and it becomes a power.

ORGANIZATION.

Concentration and organization are the effective means of progress in the beginning of the new century. Unorganized labor is being pushed to the wall by organized. The manufacturer who is not in a syndicate, trust, or something of the kind, has a hard row to hoe. He may make just as good an article, and may be able to sell it for the same price as the trust article, but then comes in the item of freight-rates which is sure to down him if nothing else will. The large concerns have larger quantities to move, and therefore can ship by car or even train load, thereby getting lower rates, to say nothing of treaties with railroads whereby special rates may be obtained.

WHOM IT HELPS.

The small bee-keeper with only a small output is the one that an exchange can help most. He is one of the small straws that are to be bound together to make the strong rope. Ten men having one-tenth of a car-load each, by organizing, can have almost the advantages of him who produces a car-load himself. The large producer gains by having small lots where they can be controlled, and not put on the market at ruinous prices, to demoralize all prices.

Bee-keepers are of necessity more or less isolated, and hence can not avail themselves of the help of organization as readily as some other callings. But even these difficulties can be overcome.

ADVANTAGES.

The advantage of lower freight, both on goods shipped by members and goods shipped to members, is one of the advantages of bee-keepers' exchanges. Also the difference between buying at retail and in car-lots or large quantities is another advantage. This will apply to all supplies used by the members, as, for example, hives, sections, foundation, cans, and barrels.

Another of the advantages of a well-managed exchange is in the uniform grading of the bee-keepers' products. Few men are capable of grading their own honey in a proper manner, for they are either too partial to their own production and grade too high, or they are too diffident of their own success and modestly put it too low, and yet others are downright dishonest and think anything they can work off is all right; whereas, an honest, capable grader has none of these influences to draw him one side and warp his judgment, and therefore can give a uniform and honest grade. One of the trials of a dealer is in not getting a uniform quality from different producers, owing to their different ideas as to grading, and if an exchange could do nothing else this one thing would pay for all the trouble.

Not every bee-keeper, however good he may be at producing good crops of honey, is a good salesman, many a bee-keeper losing heavily in mismanagement in selling what has cost him so much hard labor.

In an exchange one can have the advantage of the concentrated wisdom of all the membership in selling, by selecting one of the best business men for business manager.

Uniformity of packages for both comb and extracted honey is another of the benefits of an exchange; being all bought at the same time and place, of course all would be alike, and, therefore, many of the trials over tare on packages would be overcome, dealers would become familiar with the packages used, and know just what shape it would come to them in. In fact, uniformity is the word that expresses most of the benefits. Uniformity of products as to grading, uniformity as to packages, and, last but not least, uniformity of price.

One kind and grade of honey would always bring the same price, no matter from what part of the State it came, and not as it now is—one producer competing against another producer, or even against his *own* products, as would be the case where shipped to two dealers in the same city.

COST OF CO-OPERATION.

Everything in this life costs time, labor, or money, and a honey exchange is no exception. It will cost both money and self-denial to accomplish anything worthy of the name. Postage, paper, and some one to carry on the correspondence, must be paid for; a room large enough to store a car-load of honey in, at some central point in the State, would have to be secured, and also the services of a salesman. But in my experience with honey exchanges, which have been quite extensive and varied, all these obligations of the members are more easily met than the self-denial required to say *our* honey is not a little nicer than neighbor B's, *our* opinion is of a little more value than any one else's.

If an exchange is to succeed, there must be a full and complete surrender of individual opinion to the rule of the majority. We must think our honey just what the grader makes it, and no more. Be honest yourself, and give others the credit of being the same, and half the troubles of organization will vanish.

There are other advantages in an exchange not mentioned in this paper, and on account of its length the plan of organization has not been mentioned, although much is

to be said on that subject; but if there is enough interest to start one in Wisconsin, there will then be time enough for plans of organization. Richland Co., Wis.

Can a Queen-Bee Be Worth \$50, \$100, \$500, or \$1,000?

BY G. M. DOOLITTLE.

OF late years there seems to have sprung, from the minds of some, the idea that if they would let the world know about a certain queen-bee which they have, the only way in which this can be done is to give the estimate they place on her in dollars and cents, that, apparently, being their highest idea of expressing value. And from this it comes about, that we frequently see in print that some have queens which they value at \$25, \$50, \$100, and some even as high as \$200; and so the question has arisen in the minds of some, if there is such a thing possible as that any queen-bee can be worth these figures; and whether such expression should be an inducement to buyers.

Commenting on this matter, the editor of the American Bee-Keeper wrote as follows:

"When a queen-breeder offers as his greatest inducement to buyers to send out queens from a mother valued at \$50, 100, 200, 500 or 1,000 dollars, he should be regarded with suspicion. If he is not a fakir pure and simple, he is not what he appears to be in the eyes of the honest business world."

And what is a fakir? The Students' Standard dictionary says a fakir is "a street vender." But coupled with this is the idea, in the minds of most people, that this street vender does not scruple about recommending his goods in such a way, or in any way, which will enable him to dispose of them at a large margin of profit, relying on his ability to "hawk them up," rather than on the real value or merit there is in his goods, in proportion to the price asked for them. And this is the light in which the editor of the American Bee-Keeper looked at the matter of selling queens from a mother having only a dollar-and-cent value attached to her, according to my opinion, in reading that editorial. There is no value in a dollar. It is only a medium by which we can exchange values.

Commenting on this editorial from the American Bee-Keeper, Gleanings says among other things:

"Suppose at the beginning of the season some one should say to him [having a queen valued at from \$200 to \$1,000], 'I'll give you \$50 for that queen.' He might reply, 'I'll get \$1.00 extra on each queen of that stock. I expect to sell 1000 queens this season at that advanced price. If I hold on to her I shall be worth \$1,000 more at the end of the season than to let her go and breed from another queen. I should be foolish to take \$50 now for the prospect of \$1,000 at the end of the season.'"

If we take that comment alone, it is just such an argument as any fakir would use, and it was just the point Editor Hill was striking at, if I read his editorial aright. And such an argument does not rise much above the definition of what a "fakir" is, as given in that same editorial in Gleanings.

But, happily, Mr. Root comes to the rescue near the close of his comments where he says:

"The laurels of our [\$200] breeder do not rest solely on the long tongues of her bees. But long tongues or no long tongues, she [her bees] rolled in the honey last year, and is doing the same thing this spring in a way that eclipses everything else in the yard."

In this we have something of value expressed, while the simple saying that this queen "is worth \$200," without any qualification, (save that, because she has been "hawked" up as worth \$200, "I can sell \$1,000 worth of queens from her"), expresses no value, save that which comes from the wear and tear of the lungs doing the hawking.

But let us take this value part and look at it a little, and see if it is possible for a fine breeding queen to produce value enough, (that may be exchanged for other values), which can be represented in terms as high as \$50, \$100, \$500 or \$1,000.

Take a queen in any of our apiaries which gives bees that do as Mr. Root says do the bees from his "breeder," and if they store 10 pounds more honey than do other colonies having common queens, that extra 10 pounds of honey, according to present prices, would represent \$1.25 as food, or to exchange for value some one in some other calling may have produced, which we desire. Then, if that queen lives three years, her bees do equally as well each year,

then she has a value, speaking in common terms, of \$3.75, over and above the average queen in the apiary. If the average queen is worth \$1.00 at producing values, then this queen is worth \$4.75 for the real value of her bees, just for honey-gathering. So, then, we have it possible that a queen may approach nearly or quite to the \$5.00 point of value, just from the honey her bees may gather.

Now let us suppose that we use this queen for the purpose of rearing other queens, that we may increase on the value there is in her bees over and above others for honey-gathering purposes. And to be fair we will say, (according to the way I find it in my apiary), only one queen in four will prove as good as her mother. If we rear 40 queens from this one, and 10 of them prove of equal superiority over the average queens in our apiary, as did their mother, we have the value of that mother-queen estimated in dollars and cents as \$37.50. Now suppose we have 4,000 colonies we wish to requeen, (or we go out into the world to bless it with that number), and one out of every four proves as good as the mother, then we have \$3,750 as the worth of that queen, from the extra value in honey the bees from her daughters bring in for the mouths of those famishing with "honey-hunger" in the world.

But can 4,000 queens be reared from a single mother? Oh, yes. With our present methods of queen-rearing, it would be easy for some of our largest breeders to rear 10,000 or even 20,000 queens from a single mother. Then it is possible, by keeping this mother-queen in a nucleus of bees the most of the time, to prolong her life to five, and even six, years, as some of our breeders can testify. And thus it will be seen that the value there is in a really good queen—one that is head and shoulders above the average of those in the country—may go even much above \$1,000, as we commonly express ourselves.

But not to appear as a fakir, we should know that the queen has real value in the work accomplished by her bees and those from her queen daughters, putting that work out to the world as her real worth, rather than saying that "we value her at so many dollars." Onondaga Co., N. Y.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

BEES AND PEAR-BLIGHT.

That the bee might have carried the blight
Is a doctrine that some will endorse;
But between "might" and "did"
Quite a chasm lies hid.
The saint might have stolen a horse.

—Page 294.

REBBING A STING OFF QUICKLY.

I think Dr. Miller deserves credit for telling a questioner, 297, to dash out a sting instanter by striking the spot against the leg with a sliding motion. By not pinching the poison-bag, according to the directions usually given to beginners in the art of getting stung, one saves a little (imaginably) on the amount of poison received. But he gets a jolly increase of the amount by the time which following directions inevitably consumes. The sting, it should be remembered, is built on the model of a fire-engine, and keeps squirting as long as there is anything to squirt. And when there isn't anything more to squirt, why, then, what profit can there be either in haste or in methods of removal? People who remember and try to obey the injunction to remove a sting speedily, and to do it with a sharp knife-edge, I think they generally do so long after it is too late to gain anything by so doing.

ATTRACTIVE APARIES.

"The Home Circle," on page 298, suggests among other things this inquiry: How much pains would I take to have my apiary look nice if it stood so isolated that I was sure no one but myself would look upon it? If my power of accomplishment is small, and every day finds me compelled to choose between several things which seemingly must be done, and the one which "must be done" the most, well, then the mere looks of the apiary will probably "get left." But we will suppose the conditions are not quite so trying as that. For our own sakes we should cherish and keep alive the capacity to take real pleasure and comfort from having our things look

nice. When that capacity is gone the man has degenerated. Pain is usually an evil thing; but sometimes it is a good thing. It would be "money in their pockets," and chips of salvation in their souls, if certain persons could feel real pain in seeing how their apiaries look. Very few of us fail to be influenced in some degree by the idea of a future life; and in the light of that hope it is a shocking beastiality to allow ourselves to lose our faculties. And it is a fool's dippyancy to assume that some power over beyond will set right again all those inner qualities which we should have preserved and cultivated ourselves.

It is not likely that Prof. Cook intended to throw into very great prominence the idea of *surpassing our neighbors*. That should hardly be the leading thought. Do well, and then you *will* surpass all that do ill. If you have many wealthy and tasteful neighbors, presumably you *can not* surpass them all, and the attempt to do so will make you an ill-doer in the line of undue expense and neglect of things more important. In so far as we can rightfully take pleasure in being first, we may say, Blessed are those who *don't* live in Kalamazoo—blessed are those who live in Valley-hack! Much easier to be first in Valley-hack than in Kalamazoo. Did you ever notice in railroad traveling how sordid and unattractive things look for miles and miles, even in regions where you rather expected nice views? Well, my apiary and garden is in the Valley-hack which faces car windows; and it did me lots of good to hear of one of the car-lands remarking, "This is the nicest place we pass on our route"—plots of vegetables (and weeds) with beds of phlox between, and hives of bees, half hidden by trees, for background.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Management for Increase and Honey.

I have an apiary of 70 colonies, and would like to increase them to 140 this season. I would also like to get as much honey as possible at the same time (mostly extracted). I have enough brood-comb on hand to give each one almost a complete hive of comb. I have also abundance of extracting-combs, and a good many sections full of nice, white comb. The surplus obtained in this locality is from white clover, linden and goldenrod. The prospects for a good flow from linden are excellent. Supposing this to be your own case, how would you proceed to obtain the best results?

MINNESOTA.

ANSWER.—I don't know what will be the best way for you. What is best for one person may not be best for another. What may be best for you in one place may not be best in another. On the whole, probably the very best way would be for you to study carefully all you can find in text-books and bee-papers so as to be familiar with the whole subject, and then block out your own plans. It may be that your best plan will be to allow each colony to send out one natural swarm, and prevent after-swarms by the plan given so many times in this department, which may again be given here for the sake of the newcomers who will need it about this time of the year.

When a swarm issues hives it and set the hive on the old stand, setting the old hive close beside it. A week later move the hive to a new stand. That will strengthen the swarm, and it will so weaken the old colony that it will give up all further thought of swarming. Of course, the swarm is what will give the crop of honey, and if an excluder is put between hive and super the super should be put on as soon as the swarm is hived. If no excluder is used, then the super should not be put on for a day or two for fear the queen may go up into it.

It is possible you may prefer to take matters into your own hands, for left to themselves you are not sure that every colony will decide to swarm. This plan may suit you: Take from No. 1 all its brood-frames but one, brushing all, or nearly all, the bees back into No. 1. Fill up No. 1 with empty brood-combs or frames of foundation. Put the frames of brood in a hive we will call No. 3, and set No.

3 in place of No. 2, removing No. 2 to a new stand. Do this in the forenoon, unless you do it in the afternoon at a time when large numbers of the bees are out for a play-spell. For a day or two all the field-bees that go out from No. 2 to forage will on their return enter No. 3. If you have made no other provision for young queens, No. 3 will take the matter in charge, and will start a number of queen-cells. About a day after forming No. 3, take from No. 1 the frame of brood that you left there, and give it to No. 3, of course, giving No. 1 foundation or comb to replace it. (If you do not leave No. 1 this frame of brood, the bees may be discouraged and desert the empty hive, and if you leave it more than a day or so they may swarm.) In seven, eight, or nine days after forming No. 3, take from it one more than half its combs with the adhering bees, putting them in a hive we will call No. 4, setting No. 4 on a new stand. About a week later than this take from No. 2 frames of brood, and give to No. 3 and No. 4 one, two, or three to each, depending on the strength of the different numbers. This will strengthen your newly-formed colonies, and it will prevent No. 2 from swarming. Circumstances may make it desirable to depart from these instructions, and they are not given with the feeling that it will be right to follow them in all cases. For if No. 2 should not be strong enough to make swarming feared, it might be better to take no brood from it, trusting Nos. 3 and 4 to build up without any help, and getting as much honey as possible from No. 2.

Colonies Visited by Robber-Bees.

The season here is excellent for honey. Bees are working early and late, but fail to get ahead—in fact, are losing on account of robber-bees from a neighbor's. To make sure, I closed my hives (two in number) yesterday, and the robbers were thick; I bring a different type of bees it is easy to know where they are from. Will you kindly tell me how to destroy or get rid of them? Also, what causes bees to go robbing?

My bees have not swarmed this season, while the robbers have swarmed twice, and are filling super after super. We are told the owner feeds the bees to make them rob.

SUBSCRIBER.

ANSWER.—Your neighbor could not start bees to robbing yours by feeding his bees in his own yard. Putting feed in your yard would do more in that direction. Bees start to robbing when flowers are scarce for them to work on, and when a weak or queenless colony is within reach, especially if the hive of such colony is too open, so that the bees can not defend themselves. Exposure of frames of honey, as when hives are opened in a time of scarcity, will help to start robbing. As has been said lately in this department, if A's bees rob B's bees, B is the one to blame, and not A. You have no more right to kill your neighbor's bees that come to rob yours than you have to kill his cow that passes by on the highway. The thing to do is to keep your colonies so strong, or so closely shut in their hives, that robbers get no chance for a start at them; and, if robbing does begin, resort to the plans mentioned in your text-book, such as closing the entrance so as to allow only one bee at a time to pass, and piling up against it wet grass or hay; seeing that a good queen is present, etc.

Preventing Increase—Other Questions.

1. How would it do, to prevent increase, when the bees swarm get the queen and kill her, or take her away from the swarm and return the bees to the original colony?

2. When the bees are smoked they fill themselves. What do they do with that honey? Do they retain or deposit it where it came from?

3. Does it matter whether the bee-space is regular between the lower frames and the sections above?

4. Will the bees work above when the spaces between the frames and the sections are irregular, or partly closed by misfit of the sections?

MISSISSIPPI.

ANSWERS.—1. It will not do at all, if you stop at that. It will do all right, if you follow up the matter in the right way. If you return the swarm without the queen, in about eight days the bees will be sure to swarm again with a young queen, and perhaps two days later another swarm will issue, and there may even be three or more swarms. To prevent that you may do one of several ways. You may return each swarm as fast as it issues, and when all the queens have hatched out the swarming will cease. You

may cut out all queen-cells but one, a week after the first swarm. You may listen for the piping of the young queen in the evening of the seventh day after the swarm issued, and if you do not hear her then, listen every evening till you do, or till the sixteenth evening; when you hear piping cut out all queen-cells next morning. You may have the swarm when it issues with the young queen, and put it in the cellar till the evening of the next day, and then return it to the old hive. By that time the bees will have disposed of all the queen-cells.

2. It is probably redeposited, in most cases.

3. It matters much. If the space is less than about $\frac{1}{4}$ inch, the top-bars will be cemented to the parts over them with propolis or wax. If the space is more than about $\frac{1}{4}$ inch, burr-combs will be built and filled with honey.

4. The bees will work in the super no matter how irregular, even if half the spaces are so close together that they can not get up through them.

Using Old Combs for Swarms.

If you had empty combs that the bees had died on last winter, would you put in as many such frames as the hive would hold to have new swarms on, or would you put in some frames with only starters or foundation in them? I work for comb honey.

WISCONSIN.

ANSWER.—I would fill up with combs as long as they last. There is no better place for combs to be protected than in the care of the bees, and the sooner the bees get the combs the better.

Bees Deserting the Hive.

I had a swarm of bees leave a hive June 1. In the spring I transferred the bees from an old box into a new hive; for a while they seemed to be doing well, building up their broken combs, and were gathering honey. About noon June 1 they left the hive, taking the queen, young and old bees with them, and leaving unsealed fresh honey, young bees just gnawing out, and bees in the larval state. There were no mice or ants to bother them. The hive was clean, and they had plenty of honey, and when I looked in the hive there were only five or six bees—robbers, I suppose.

COLORADO.

ANSWER.—I don't know what the trouble was. Very likely it was a case of what is called spring dwindling. I have had colonies desert their hives just as you did, leaving honey and brood in all stages, with no apparent excuse that any self-respecting colony would give for leaving, and the only thing that I could guess in the case was that the old bees had died off, and there was more brood present than the young bees could take care of. You may have trouble of the same kind again, and you may not have another case in years.

Too Rapid Increase—City Bee-Keeping.

I started the season with four colonies, which, up to date, has increased to ten, and one ready to swarm. I have one colony that is working in the supers. We have plenty of white clover, and I think will get some honey soon.

1. I have one colony which has cast two swarms, that seems to be about half drones. What is the cause of so many, and what will be the result if let alone?

2. My bees are a good quality of Italians—the best in this section. I live in the city, and don't branch out very strong. Now, what would you advise me to do? I am a dry goods clerk, and have not much time. I can sell a few colonies now. Would it be a good idea to rent pasture close to town, and try to take care of the over-supply, or not?

ILLINOIS.

ANSWERS.—It may do no great harm before answering your questions to make the gratuitous suggestion that you may make the mistake that many a beginner makes, and increase too rapidly. When you increase from four to ten or more, your colonies will not be as sure to live through the winter as if you were satisfied with a more moderate increase. Neither will you get as much honey. Of course, if you are anxious for increase, and will give them the proper care, feeding all that is necessary, you may pull through all right.

1. If the drones are so plentiful immediately after casting the swarms, the trouble probably is that there is a great

deal too much drone-comb in the hive. If the drones appeared in plenty not until two months or so after the last swarm issued, then the trouble may be that you have a drone-laying queen, or laying-workers. If the trouble is from too much drone-comb, then your bees will gather less honey than they otherwise would, and much of it will be wasted in rearing and feeding those useless consumers. If laying-workers are present, or a drone-laying queen, it means the destruction of the colony.

2. What do you want to rent a pasture for? If you mean for the bees to feed upon, they will not thank you to rent it, but will find it if it is within two miles of your home. You can keep in a city yard as many bees as can find pasture within reach.

Bees Not Working.

Bees are building up fast. I have a colony that has a queen, but the bees work hardly at all, scarcely any of them coming out. What is the matter? They have some honey. I will Italianize about the middle of this month. I lost heavily the last winter, because of short stores last fall.

OKLAHOMA.

ANSWER.—There may be nothing the matter except that the colony is very weak. The presence of a queen can not of course warrant a goodly number of bees flying unless there are plenty of bees present. Look and see whether the queen is a drone-layer. If not, you will probably see bees flying well as soon as the colony is a little stronger. If it should turn out that there are plenty of worker-bees in the hive, and very few of them flying while other colonies are busy, then it may be well to change the queen and give them one of more industrious stock.

Perhaps Pickled Brood.

I bought five colonies of bees this spring in movable-frame hives. Three of which I looked into and found dead brood, which looks watery, and lies on one side. There is no smell about it yet. It doesn't seem rubbery, or anything like that, and will not draw out with a toothpick. Will the swarms have the same disease? What will become of foul or pickled brood if not attended to? What can be done for them?

NEW YORK.

ANSWER.—When anything so serious as pickled brood is suspected, it is too serious a matter to be treated by a few words in this department, especially as it would take up too much room. Study up the subject fully in back numbers, and get the leaflet on pickled brood, if you do not have it already. Very likely as honey comes on now plenty you will find the disagreeable symptoms largely to disappear, but none the less you should inform yourself so as to battle it, for it will be a safe thing to count on its reappearance in the future.

Thinks Late Thin Honey Injures the Bees.

There is a plant here that has yielded honey in October for the last two years. The bees have filled the brood-chamber full of this thin honey, and when they had the first flight in the spring they soiled the hive badly, both inside and outside around the entrance. I lost half of my bees, and the other half are weak. It seemed to affect the queens. I would like to know how to keep this thin stuff out of the brood-chamber. If I put sections on would they not put it in the brood-chamber as long as they had room? How would it do to run it through the extractor without uncapping it? If there would be any brood in the hive at the time would it not kill it? I believe the honey is from the asters.

OHIO.

ANSWER.—I'm afraid I don't know enough to help you out. There is a possibility that you may be mistaken about the honey from that late plant being the cause of the mortality among your bees. But if you are satisfied that extracting without uncapping would help matters, you can do so without hurting the brood. So long as you do not turn the extractor fast enough to throw out the brood you are all right.

The Premiums offered this week are well worth working for. Look at them.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

The Treasures of Nature.

"From the drift of a star to the drift of a soul,
The world is all miracle under control;
The butterfly's wing and man's reverent awe,
Alike wear the chain of inscrutable law;
A law that allures us, but ever eludes,
That baffles our groping, but never deludes;
We never can hold it; it holds us secure;
And the wisest in reading shall longest endure;
A Faith-bow of promise, a promise replete—
Forever fulfilling, but never complete;
We chase where it beckons, and gather the gold,
And lo, on before us, new treasures unfold!"

THE STUDY OF NATURE.

In my teaching in college, I find in some of the students an almost insurmountable disinclination to the work of dissecting insects, and they come with no alacrity to the work of dissecting. Others, no whit less refined and sensitive, in a general way, show no such squeamishness. We dissect cats at first, and then other animals. I regard this knowledge secured, not from books but from handling the real things, as of great value. The same is true in regard to the study of caterpillars, beetles, and bugs. The distaste is often erratic in the extreme. Thus nearly every girl will take into her hand, even at first, the beautiful, little lady-bird beetles, while she will shrink away appalled at a ground-beetle or caterpillar—will shudder if a myriapod is handed to her, and actually turn pale at the very thought of touching a spider. I think all this unreasoning, and unreasonable distrust, is unfortunate. The possessor, unless cured of it—and it is a malady difficult of cure—will lose much of the beauty that she would otherwise get. Every girl may be required, as a duty, to dress a chicken or a rabbit; to dissect carefully a cat will teach her to do the other more intelligently, and will give her an insight into her own structure and physiology that will be of great value, and which can be gotten in no other way.

The insect world touches us in many ways. They annoy us and our domesticated animals. They prey upon our crops to the annual tune of millions of dollars. The best success in life demands that every home circle shall know—and so study—these myriads of friends and foes—for all are not enemies—that they may prepare to wage battle in case the intruder comes with intent to injure. Insects are ubiquitous—that is, everywhere. We run against them at every turn. Not to know them is surely most unwise neglect. Indeed, that man is best equipped who knows most about the things that he runs against in all his daily walk. The little malarial animal is very small, but it can destroy the red blood corpuscle. To know of it and its work enriches the world. To know that a mosquito inoculates us with this often fatal protozoan, by its bite, is even more valuable, for it shows us how we may fence off disease and even death.

Thus this knowledge of these hosts that everywhere encompass us about is vastly practical, and stupid indeed is he or she who does not grasp every opportunity to gain such knowledge.

Again, no study does more to quicken and develop observation than this. The person who sees everything, and sees it well, is mightily strengthened for life's big fight. As students work in geometry, they often say that they can almost feel their brains grow. So students of entomology often remark, on their increased facility to find insects, and to find and see correctly minute and obscure parts, as the study goes on.

Just here is suggested a duty for every home circle. I have shown before the value of the walk in the woods, the Sunday stroll with the children by wayside and meadow. These are very golden days to foster this love of nature. They are often times when it is hopelessly crushed. The mother, mayhaps, is taking her first walk with the little boy or girl. They come upon a lovely caterpillar or beautiful beetle. The mother shrieks and jumps back. The little one

has a lesson and an impression that it will take long schooling to correct. It has then and there gained an abhorrence that will rob it of great pleasure, and will very likely prove a handicap in life's work. I have always rejoiced that my mother was not appalled at the sight of grub or spider, and that she early taught me to see the beauty in both. I shall never outlive the pleasant memories which came with teaching my own little ones to admire and love these gems, sown so thickly about us by God's own loving hands. I rejoice the more as I know that my dear ones are much better equipped for life's journey, and are much better prepared to get more of pleasure and profit from it.

I urge all in our home circles to be interested in everything about them, to study and observe, and I am free to say that nothing offers so rare an opportunity as these myriads of wonderful insect forms, of which our honey-bees stand at the head. I question if we can bequeath a more blessed legacy than to awaken in the minds of our children a love for and interest in these gems of the landscape. No father or mother is foolishly employed who spends generous hours in encouraging the little ones to just such observation and study.

In a future article I will give some hints as to methods of procedure. I will explain how valuable collections may be made, and how such work begets a love of nature, order, and beauty.

THRIFT.

Thrift, I take it, is earning more than we spend, and never purchasing until we can pay. That is what my father taught me. He urged it as a most important rule of life. Does not our friend, Mr. Doolittle, recognize this as a certain basis of happiness? The thrifty—honestly thrifty—man holds his head higher, walks more erect, feels more self-respecting, is more a man. While thrift may not be, is not, the best gift to covet, it is a worthy one. So of our nation. She for the past few years is purchasing far less than she sells. That is, her income is far in excess of her outlay. In other words, her exports of bread-stuffs, manufactured articles, and raw materials, are far in excess of her imports—of tea, coffee, sugar, and such other articles as she needs. She is thrifty. And Mr. Doolittle and I are both rejoiced. We are happier than though she were buying more of value than she were selling.

I believe Mr. Doolittle is exporting in excess of his imports. That is, his honey-sales, etc., are greater in amount than his purchases of clothing, supplies, etc. Thus he, like our goodly country, is thrifty. I rejoice that it is so.

I hope this explains my logic. I regret that I did not make my meaning plain to all before. I thought as I commenced reading Mr. Doolittle's criticism that he was going to say: Why rejoice for our thrift means unthrifty for our neighbors across the water? I do regret that. The entire world looks enviously at our commercial progress. They are alarmed at our increased thrift. They watch our continued and rapidly increasing prosperity with almost consternation. That should make us no less energetic, or frugal. It should make them hasten to study our methods, and to adopt our practice.

QUESTIONS AND SUGGESTIONS.

Mr. Doolittle's kindly paragraph causes me to urge others to ask questions and make suggestions as to these "Home Circle" papers. I wish to make them helpful to all the readers of the "Old Reliable." One reader kindly urged me to read Henry George's "Progress and Poverty." This friend actually sent me the book. I am studying it carefully, and when it is digested I shall bring it into "The Home Circle." It has valuable suggestions.

Will not all contribute? Send me valuable recipes, hints as to living and economies, gems cut from newspapers—and every thing that will help to make our homes more bright and happy. Send to me thus: A. J. Cook, Claremont, Los Angeles Co., California.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

\$15,000 in Cash to be Given Away

Copyrighted
by the
Press Pub-
lishing
Association.

The Press Publishing Association will give \$15,000 in 1,000 Cash Prizes to those making the nearest estimates on the combined Official Vote of Ohio, Massachusetts and Iowa, cast for Governor on the 5th day of November, 1901.

Estimate the total vote in these three States combined for Governor and send your estimate and subscription to the American Bee Journal, and you will receive a certificate, which will entitle you to participate in the distribution of the \$15,000 to be awarded by the Press Publishing Association, of Detroit, Mich., to those making the nearest estimates of the Official Vote for Governor in the States of Ohio, Massachusetts and Iowa, to be determined by the Election held on the 5th day of November, 1901.

We have made arrangements with the Press Publishing Association, of Detroit, Mich., to enable our subscribers to participate in the distribution of these magnificent prizes, amounting to \$15,000.

Our Offer: Until Further Notice, every one who sends us a sufficient amount to pay his or her subscription to the American Bee Journal to the end of this year (1901,) provided the subscription is in arrears at least since Jan. 1, 1901; or to any one sending us \$1 for a year in advance of next Jan. 1, 1902, will receive a certificate which will entitle him or her to participate in the distribution of the Prizes. No advance is made in the price of our paper; you get the certificate absolutely free.

YOUR ESTIMATE.—When you send in your subscription you also send your estimate. Be careful to write your name, address and estimate as plainly as possible. As soon as we receive your subscription we will send you a certificate of the Press Publishing Association, of Detroit, Mich., containing your estimate, which will insure you any prize your estimate may entitle you to claim. We will file a duplicate certificate with the Press Publishing Association. Every subscriber may make as many estimates, and will receive as many certificates, as he sends dollars on subscription to the American Bee Journal.

Valuable Information. To aid subscribers in forming their estimate, we furnish the following data:

The combined Official Vote in these three States in

1891 was.....	1,537,493	
1892 was.....	1,084,420	increase 9.56 percent
1893 was.....	1,016,487	decrease 4.04 percent
1894 was.....	1,533,887	decrease 5.10 percent
1895 was.....	1,576,452	increase 2.77 percent
1896 was.....	1,726,718	increase 22.22 percent
1897 was.....	1,572,109	decrease 18.40 percent
1898 was.....	1,532,540	decrease 2.52 percent
1899 was.....	1,653,389	increase 7.89 percent
1900 was.....	1,705,610	increase 18.88 percent

The certificates of the Secretaries of the States named showing the Combined Official Vote will determine who are entitled to the Prizes, and the awards will be made within 30 days after the Official Vote is known.

The American Bee Journal will publish the names of the successful Estimators.

Statement of Mr. W. A. PRINGS,
President of the Central Savings Bank, Detroit, Mich.:

I HEREBY CERTIFY, that the Press Publishing Association has deposited \$15,000 in the Central Savings Bank, Detroit, Mich., for the express purpose of paying the Prizes in their contest on the Combined Official Vote of the States of Ohio, Massachusetts and Iowa, and that this fund can be used for no other purpose.

W. A. Prings

President Central Savings Bank, Detroit, Mich.

PRIZES to be Awarded as Follows:

To the nearest correct estimate.....	\$5,000
To the 2d	1,000
To the 3d	500
To the 4th	300
To the 5th	200
To the 6th	100
To the 7th	75
To the 8th	50
To the 9th	25
To the 10th	15 each = 150
To the next 35 nearest	10 each = 350
To the next 142 nearest	5 each = 710
To the next 160 nearest	4 each = 640
To the next 180 nearest	3 each = 540
To the next 200 nearest	2 each = 400
To the next 260 nearest	1 each = 260
Total, 997 prizes, amounting to	\$12,800

In addition to the above Prizes, the following Special Prizes will be paid.

To the person making the nearest correct estimate before July 10	\$1,000
To the person making the nearest correct estimate between July 10 and Aug. 10	700
To the person making the nearest correct estimate between Aug. 10 and Sept. 10	500
Total, 1,000 prizes, amounting to	\$15,000

In case of a tie, or that two or more estimators are equally correct, prizes will be divided equally between them.

UNTESTED

Italian Queens Free

BY RETURN MAIL.

For sending us One New Subscriber for one year, to the American Bee Journal, with \$1.00, we will send, by return mail, a fine Untested Italian Queen free as a premium. This offer

Good Honey-Flow Expected.

We have just had a couple of good rains, and it looks as if we would have a good, old-fashioned flow of white clover honey. We have had no rains to amount to anything for nearly two months, and I had about given up hopes of a clover crop. A. N. DRAPER.

Madison Co., Ill., June 7.

Drouth Will Cut the Honey Crop.

Our bees have been storing honey nicely for about two weeks, but the protracted drouth will cut our honey crop short, as the white and alsike clovers are drying up or dying, and there is but little sweet clover growing near. DAVID SHARP.

Cass Co., Mo., June 8.

Bees Did Not Winter Well.

The bees came through the winter very weak indeed, but have built up much better than I expected, so I can hope to get something, at least. MATHILDE CANDLER.

Grant Co., Wis., June 6.

Keeping Down Increase.

I see a good chance for Dr. C. C. Miller to get into a dispute in regard to an answer to a question on page 328, in which he says: "If your object is to keep down increase, perhaps this plan might suit you better: When the colony swarms kill the old queen and return the swarm. A week later cut out all the queen-cells but one, and the work is done. There will be no more swarming for that colony until another year."

That may be so in some locations, but it will not work everywhere, as I have had swarms many times after hiving first swarms by themselves and cutting out every queen-cell but one 7 days after the swarm issues. And I have then had swarms from the same colony again in from 6 to 8 weeks. I also have virgin swarms from almost every prime swarm. H. HARLAN.

Kanabec Co., Minn., May 27.

Good Outlook for a Honey-Crop.

My winter and spring losses have been very heavy and it has been cold with much cloudy, rainy weather (it is raining to-day), and the wind seems to hang in the northeast. But the honey outlook is fine; clover is very plentiful as none of it was winter-killed, and basswood seems to be setting full. The biggest drawback with me is the bees, but they seem to be building up fast now, and may be in good condition for the flow.

I visited R. L. Taylor's apiary, May 25, and his 200 colonies are in excellent condition, most of them ready for the flow. With the clover flow two weeks ahead. He wintered his bees in the cellar, and I wintered mine outdoors. E. B. TYRRELL.

Genesee Co., Mich., May 29.

Long-Tongued Bees.

From a Southern standpoint I read with some satisfaction G. M. Doodittle's article on page 235, and Dr. Miller's reply on page 235. I feel quite sure that Mr. Doodittle is very willing that the people of the red-clover belt shall get the benefit of this bloom, and am also sure that he meant to cast no reflections on the honesty of the people at Medina. I am of the opinion that these articles will do good. While no sensible man will doubt the advisability of having long-tongued queens in some locations, there are other places where no benefit whatever would be derived from them. In my own locality (southern Georgia) bees with a 25-100 reach would store

no more honey than our shorter-tongued bees, other qualifications, of course, being the same. Although Root closes his advertisement with an "S. B.," saying that the rank and file of beginners have no use for such queens, still they will buy them, and it was this class of bee-keepers that Mr. Doolittle was desirous to *help*.

If some enterprising queen-breeder will get up a non-swarming strain, a greater benefit will be conferred upon the bee-keeping fraternity than tongue-speech. By this improvement all of us, from the red clover fields to the orange blossoms, and from buckwheat to sage of the West, will jump for joy.

Hurrah for long-tongued queens, for Dr. Miller and the red clover folks; and hurrah for bees that don't swarm, for "we" uns!—
Dodge Co. (Ia.) F. M. CRIGHTON.

Best Honey-Flow in Years.

Bees are booming on white clover, and the honey-flow is the best we have had in years. White clover is literally taking the country, for which I am sorry (!).

We are in sad need of foul-brood legislation in this part of the State.

W. T. STEPHENSON,
Massac Co., Ill., May 31.

At Work on Raspberry and Clovers.

Bees are working very busily on raspberry, white clover, and red clover, both clovers being in bloom now. The prospect for basswood is not as good as in former years, but the clovers are better.

L. G. BLAIR,
Grant Co., Wis., June 3.

Bees Will Not Eat Pasteboard.

Tell Dr. Miller that bees will not eat pasteboard in this country, so I lost one of the queens he sent me last year. The other one is doing well.

Bees wintered poorly, but are doing nicely this spring.

J. KENOVER,
Whitman Co., Wash., June 1.

"Are There Any Queen-Breeders?"

This is the heading of an article in the Progressive Bee-keeper, by F. L. Thompson, in which he says:

It is about time that bee-keepers understood that queen-breeders are a different class from queen-rearers. There are plenty of queen-rearers, who will tell you they breed queens by the most approved methods—artificial cups, nurseries, specially prepared colonies, and what not. But rearing is not breeding. Are there really any queen-breeders? I think there are a few! really don't know whether there is one who applies those principles of selective breeding which good stock-breeders do.

Inbreeding.

This has brought ruin to many an apiary where bees were left entirely to themselves, the bees "running out" for want of fresh blood, and yet some of the greatest triumphs of scientific breeding have been through that same inbreeding. The following from the Rocky Mountain Bee Journal is by F. L. Thompson:

It is well known that stock-breeders practice inbreeding largely, in order to secure a greater proportion of prepotent individuals, and a higher degree of prepotency, than would be the case by watching for chance sires. But there is a popular idea that inbreeding is bad, very bad. There is some truth in the popular idea, but also considerable error. Hence, it will pay to be posted

of trains, etc. 11-24AT

also on inbreeding; for even now some queen-
breeders largely control the drones, and hence
could, and perhaps do, practice selective in-
breeding; and in the near future it is prob-
able that mating in confinement will be at-
tained, whereby the drones will be absolutely
controlled.

Now, the experience of the best authorities
is that inbreeding is not, in itself, of any
detriment whatever. The instances of vigor-
ous animals which have been inbred for many
generations are too numerous to mention. The
idea is altogether true, for this reason: If
the two parents have any common tendencies,
their offspring will have those tendencies
doubled. Of course, this is more liable to
happen with related parents than when they
are not related. Hence, if any of those com-
mon tendencies which they will be approxi-
mately twice as bad in the offspring. On the
other hand, if they are good, inbreeding has
none but good effects.

The practical application of this, is that if
one wants a fixed and prepotent strain of
bees, the breeder who breeds closely is more
apt to be able to furnish it than those who do
not, always providing, and this is important,
that he is thoroughly acquainted not merely
with the details of queen-rearing, but also
with the application of the principles of
selective breeding. It should be remembered,
also, that there are various degrees of in-
breeding. To mate parent and offspring has
only half the effect, for good or evil, of mat-
ing brother and sister. At present, on the
whole, it may be better to avoid stock in bees
likely to be inbred, but as soon as queens will
be mated in confinement, the case will be
altered.

Best Averages from New Colonies.

A Stray Straw in Gleanings in Bee-Culture
says:

Sometimes it is said that a beginner gets a
yield of honey which he never after equals, be-
cause his first enthusiasm is gone. I believe
that's a libel on many of the veterans. A bee-
keeper may ride his hobby so hard as to kill
it, but they don't all do it. Just 40 years ago
I took the bee-fever, and the temperature is
just as high now as it was then. In looking
forward to some things I want to do with bees
next summer with just as keen a relish as I
had 40 years ago. The extra results achieved
by a beginner are largely to be credited to the
fact that he has a small number of colonies,
and so the bees have a better harvest. [Your
last sentence explains it. In the "ABC"
book the statement is made to the effect that
the average yield per colony will be much
larger in a small apiary, remote from any
other yard of bees, than in larger apiaries.—
EDITOR.]

Wax-Worms in Pure Wax.

It has generally been considered that pure
wax, as in foundation, is in no danger of
being troubled by the wax-moth, at least some
pollen being necessary to support the larvae.
G. M. Doolittle reports in the Progressive Bee-
keeper that he found the work of wax-worms
in foundation that had been kept in a warm
place near the roof.

Sweet Clover Not a Weed.

The following question and answer appeared
in the Wisconsin Farmer:

MR. EDITOR:—Will you please tell me all
about sweet clover? I would like to know
whether it is good as a fertilizer or pasture or
whether it is good for nothing. Some tell me it
is nothing but a weed. Others tell me it is the
same as red clover.

ANS.—Sweet clover, *Melilotus alba*, is a
legume, as are other clovers, and because of
this fact exerts a similar effect in the renova-
tion of worn-out soils. In the North, generally,
it is regarded as a weed. Some States have
legislated against it as one of the noxious weeds
to be destroyed, along with the Canada
and Russian thistles. In the South one or two
experiment stations have commended it, both
as a forage-plant and as a source of fertility. It
very early becomes woody, and loses whatever
value it has as a forage-plant. It has a peculiar
taste of its own, to which cattle have to become

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

accustomed before they will eat it; generally they have to be starved into eating it. While there are some differences of opinion about the place the sweet clover should occupy, our judgment in regard to it in the middle West is that it is a weed, which only means, according to the old definition, "a plant out of place."

It is our opinion that the plant is not so much "out of place" as the man on whose farm it grows; for the man in this age who has not learned the value of sweet clover as a farm crop would better not farm until he has called on some intelligent bee-keeper who can tell him the value of this wonderful legume. Another man would seem also to be "out of place," and that is the agricultural editor who does not know any more about sweet clover than this answer would indicate.—E. T. ABBOTT, in Modern Farmer and Busy Bee.

Feeding in the Open Air.

This is objected to because colonies that need least get most, and because neighbors' bees can not be excluded. It has the advantage that it seems a little more like a natural harvest than feeding in the hive. M. A. Gill says in the Rocky Mountain Bee Journal:

I hardly dare advise beginners to feed in the open air, but practice that plan myself. I feed in troughs filled with alfalfa stems, or open vessels with a piece of burlap thrown over to prevent the bees from drowning. I feed at 2 to 3 o'clock p.m., giving each colony from one-half to a pound of honey or syrup made as thin as raw nectar. After feeding in this manner for a couple of days, if I have any brood-combs filled with honey, I uncap them and hang not more than three in an empty hive, equally spaced apart, and let the bees have it. If properly done, there will be no trouble from robbing. I had as soon feed 100 colonies in the open air as 100 pigs, provided my neighbors do not have too many bees.

The Lowest Temperature for Comb-Building.

S. E. Miller reports in the Progressive Bee-Keeper that he had comb built in March when the outside temperature varied from 18 to 72 degrees, the average being about 45 degrees. He asks what is the lowest temperature at which comb-building can be carried on, and answers from three different men are given. J. W. Rouse frankly says he does not know, but thinks it can hardly be below 50 degrees. G. M. Doolittle says that bees can build comb in zero weather. Dr. Miller goes still lower, and practically says that no colony of bees has ever lived through a temperature so low that it would not admit of comb-building. Mr. Doolittle says the heat inside the cluster necessary for comb-building and brood-rearing is from 90 to 98 degrees, and Dr. Miller explains how it is that the colder the weather the warmer it is in the center of the cluster. His answer is as follows:

If you mean at what temperature of the brood-nest bees can build comb, it may be replied that it is somewhere in the nineties, probably. From your accompanying remarks, however, it seems that you mean the temperature of the atmosphere surrounding the hive. That's another thing, and the temperature depends somewhat upon the strength of the colony.

If a single bee is exposed to a freezing temperature, it will be a dead bee in a short time. Possibly it might not be called a dead bee, for it can be revived if brought into a warm place if it has not been left frozen too long. If there be a cluster of bees, the bee in the center of the cluster will not succumb to the cold as soon as a single bee, but it will succumb. If there be 50,000 bees in the cluster, with plenty of stores within easy reach, a freezing temperature will not affect them unfavorably at all. And a much smaller cluster

than 50,000 will withstand without injury the same temperature.

Somewhere between the single bee and the cluster of 50,000 there must be found the smallest cluster that will withstand a temperature of 32 degrees, and a cluster of any less size will succumb. What the size of that cluster is I do not know. I wish I did.

It is also true that a cluster of 50,000 bees will stand a temperature much lower than 32 degrees, for bees, to a certain extent, make their own temperature. Somewhere in the neighborhood of 50 degrees is as low as bees seem to like in winter, for the temperature of the outer part of the cluster. When it gets below that there will be a stirring of the cluster to increase the heat, each bee being a little furnace with honey as fuel.

Suppose that the air surrounding the cluster is 40 degrees. Suppose also that the temperature of the cluster is 50 degrees, and that the bees are entirely dormant. In that case it is quite clear that the cluster will gradually cool down till it is of the same temperature as the surrounding air. But the bees are not dormant, and they will at once proceed to bring up the temperature. Just as soon as the cluster is warmer than the surrounding air, heat will be given off from the cluster, and a continual production of heat will be necessary to replace that which is lost by radiation. That radiation is always of necessity from the outer surface of the cluster, so the outer surface will always be cooler than the center, in other words, the center will be somewhere above 50 degrees.

Now, suppose the outer temperature keeps getting lower and lower. The lower it gets the more rapid the radiation from the surface of the cluster, and the heat in the center of the cluster that was sufficient when the surrounding air was at 40 degrees will no longer suffice. So the heat must be increased in the center of the cluster, and when the outer air becomes cold enough the heat in the center of the cluster will rise to that of summer, and we have the paradox that the colder the weather the warmer the cluster.

It must not be understood that the heat in the center of the cluster must depend entirely on the surrounding temperature. Anything that excites the bees to greater activity will increase the heat of the cluster, so that temperature may be brought up at any time; but as the outside temperature lowers, the inside must be brought up, if the colony is not to perish.

With these principles fairly understood, we are ready for the question, "What is the lowest temperature of the air surrounding the cluster that will allow the bees to build comb?" The answer is, "The colder the air surrounding the more nearly will the heat of the cluster be to the point of comb-building, so there is no degree of cold so severe that comb-building may not take place unless so severe as to stop all vital action, a degree that is never reached under the natural conditions when a strong colony has plenty of stores within reach."

It may occur to some one to inquire: "Why is it we are so constantly told that about 45 is the proper temperature for a cellar, if 50 degrees is the temperature to which the cluster must be raised? Why not have the cellar at 50 degrees, and save the bees the trouble of the additional 5 degrees?" The answer is easy. Practically no one has shown that bees are quieter at 45 degrees than at 50 degrees. That answer may silence, but with some it will not fully satisfy. Well, then, the answer may be something like this: The bees are never entirely dormant, so they are always producing a little heat, and if the surrounding air is at 45 degrees, then the additional heat produced by the bees will run it above 50 degrees. Moreover, it is not possible to keep the air of the cellar constant, and if it is a little too cold the bees can bring it up, but if it is too warm they can cool it down.

A Home in Colorado FOR SALE

I have a fine Fruit-Ranch of 14 acres here at Fruita, all set to the fruit, principally winter apples, with plenty of small fruits, peaches, pears, plums, cherries, apricots, prunes, and about 700 grapes; 100 colonies of bees, mostly Italians, and about 100 fine Belgian hares that I will sell with the place. The orchard is in fine bearing, being about 10 years old, and is clean and free from weeds. The house is a good 7-room one, nearly new, with bath and water; a good new barn for two horses and two cows; good brick hen-house and two good cellars, good lawn and shade. I have a paid-up water-right with the place, with an abundance of water at all times for irrigation. I am desirous of making a change in my occupation, and will sell the place at a bargain. With the proper party the yield from the place this year will be about \$2,000. It joins up to within 20 rods of the town site of Fruita, where we have one of the best high schools in the State, employing 7 teachers. It is only 1½ miles to the depot, churches, school and post office, and has telephone connections with all parts of the State. This is a good, healthy climate, and good society.

Address for terms and further particulars,

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, June 7.—Not any new comb honey has come to this market up to date hereof, but promises are being made for some before the month closes. A little good white comb still on sale, which easily brings 60¢; not much of any other kind here. Extracted very dull, practically no sales made. Beeswax firm at 20¢.
R. A. BURNETT & CO.

DETROIT, June 8.—Strawberries are taking the attention, and very few sales of honey are made, but prices seem to keep up on good lots. Beeswax in fair demand at 27¢-28¢.
M. H. HUNT & SON.

CINCINNATI, May 17.—No demand for comb honey, also stock of it very exhausted. Extracted very dull; sales are more or less forced; lower prices from ¼ to 1 cent per pound.
C. H. W. WEBER.

BOSTON, May 21.—Our market continues dull on honey with very light stocks on hand. Our normal prices are as follows: Fancy 1-pound cartons, 17¢; A No. 1, 16¢; No. 1, 15¢; No. 2, 14¢. Extracted from 6¼ to 7¼¢.
BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-framed cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00.
FYECKE BROS.

NEW YORK, June 1.—Extracted honey is exceedingly dull and very little moving. We quote for the present: White, 6½¢; light amber, 5½¢; amber, 5¢. Some demand for comb honey at unchanged prices. New crop is now beginning to arrive from the south, and sells at from 12¢-15¢, according to quality and style.
BEESWAX, 27¢.

ALBANY, N. Y., June 1.—Honey market quiet. No stock, no receipts, and no demand now. It is between seasons. We look for good prices the coming season, for in this vicinity the foal brood has nearly exterminated the bee-keepers.
H. R. WRIGHT.

BUFFALO, May 29.—Very light trade in all grades of honey. Strictly fancy sells fairly, at 14½¢; dark dull at any price, and 80¢-90¢ above the range. Beeswax, fancy, 27¢-28¢; dark, 23¢-25¢.
BARRON & CO.

KANSAS CITY, May 4.—Practically no shipments arriving, and very little selling. We are getting \$3.50 to \$3.65 per case of 24 sections No. 1 white; amber, \$3.00 to \$3.25. Beeswax scarce at 25¢.
W. R. CROMWELL PRODUCE CO.,
Successors to C. C. Clemens & Co.

SAN FRANCISCO, June 5.—White comb, 11½¢; 12½¢; amber, 10½¢; dark, 9½¢; light amber, 4¢; amber, 3½¢-4¢. Beeswax, 26¢-28¢. Dealers are very bullish in their ideas, but are not securing much bottom for the prices here. In a small way to special trade an advance on quotations is being realized.

For Sale 200 CRATES OF 2 60-pound cans each; been used once; in good condition; in lots of 10 crates, 35 cents a crate.

Illinois Day at the Pan American Exposition.

Tuesday, June 25, 1901, has been selected
by the Governor of Illinois, as
"Illinois Day," at the Pan-American
Exposition at Buffalo. In order to
make that occasion a greater success,
the Nickel Plate Road will lend its assistance
by making the following rates:

\$13.00 for tickets good 10 days.

\$16.00 for tickets good 15 days.

\$21.00 for tickets good 30 days.

Tickets at above special rates will be
available on any of our three through
daily express trains from Chicago at
10:35 a.m., 2:30 p.m., and 10:30 p.m.,
which carry through vestibuled Pullman
sleeping-cars and afford excellent
dining-car service, on the individual
club meal plan, ranging in price from
35 cents to \$1.00.

For further information and illustrated
descriptive folder of the Pan-American
Exposition grounds, write
John Y. Calahan, General Agent, 111
Adams St., Chicago. 13-24A2t

I ARISE

Editor.

CHICAGO, ILL., JUNE 27, 1901.

FORTY-FIRST YEAR
No. 26.

WEEKLY

** Dr. C. C. Miller **

June 10, 1831.

June 10, 1901.

AND so to-day I'm seven times ten,
And hence 'tis said I live on "borrowed time."
Well, what do I have that was not lent
By Him who made me what I am?
My life, and all that goes to make it up—
From deepest joy to sorrow's cup—
These all are borrowed from His gracious store.
But some day He will *give* me better things—
Yes, the best He has, and they shall all be mine
Throughout unending ages.
You say I'm on the "shady" side of life.
Not so, my friends: the shadows are behind,
Along with all earth's troubles.
I see ahead the Sun of Righteousness,
Whose beams already light my path.
And render it more pleasant to my tread
Than aught that this world has to give.
But even if the shadows do at times
Fall o'er my pathway, dark and deep,
I'll pause a moment, wipe my brow,
And then press on, not to the light,
But in it and toward it.
The best of life is still ahead,
And, I am sure, it always will be so:
For morrow's sun has something for the child of God
Far better than the things to-day has brought;
So don't condole with me on ripening age.
For that is but another name for labor done,
And an advance toward that gladsome day
When we shall gather up our jewels,
And we, in turn, as jewels, shall be gathered up.

W. P. Root

MEMBERSHIP DUES, \$1.00 a year.

☞ If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

DR. C. C. MILLER, of course, is different from some ladies in the usual number of particulars, and also has another distinguishing dissimilarity. He still has birthdays. He had one the 10th of this month. He is now 70 years old—or, we should say, 70 years young, for he's on the sunny side of 70 now. At least he would tell you that if you were to ask him on which side he is.

□ Mr. W. P. Root, known as "Stenog" in Gleanings in Bee-Culture, has sent us the poetic statement on the first page of this number. He has expressed for Dr. Miller quite clearly just what the Doctor could say, though perhaps in a different manner.

Dr. Miller is the most prolific writer on the subject of bee-keeping to-day. He has been in the bee-business over 40 years. And he doesn't claim to know it all yet. To many a question relating to bees and bee-keeping he is compelled to offer the laconic reply, "I don't know." And yet his fund of actual information, gained from his years of practical experience in the apidary, is something remarkable.

Further, we were going to say that Dr. Miller is the best loved bee-keeper in America, but we won't say it, for the Doctor wouldn't thank us for it. He is the quintessence of modesty, and so we must not say too much at this time. And yet to say the good and well-deserved thing now is much better than to wait and place them in bouquets upon the easlet that some day will contain all that is mortal of him.

We can truly speak not only from our own heart, but for many others, who appreciate Dr. Miller, his life and work, and pray that he may be spared to us 'up higher' as he is called "up higher."

MR. R. WILKIN, one of the oldest and most prominent bee-keepers of California, died at Newhall, Calif., May 30, 1901. He was father-in-law of J. F. McIntyre, another leading bee-keeper of the same State. We hope soon to be able to present a more extended sketch of Mr. Wilkin in these columns.

MR. JOHN W. BAYCUMMAN'S East Side apidary is shown on page 410 this week. It is located in Fairfax Co., Va., and all but two of the hives used are the double-walled. The apidary faces east, and is beautifully situated. The little girl at the first hive is his youngest daughter, and the lady to the left is Miss Castell, his helper in the apidary. Mr. Bauckman says she can find a queen as quickly as the most experienced apiarist, and is a good bee-keeper, besides being a fine seamstress. The two lads in the background, carrying the colony of bees, are his two sons who are running the farm. The lady to the right is another daughter, and the man with the smoker is Mr. B. himself.

He thinks his hives are the finest in the United States, as they are a perfect piece of cabinet workmanship, being thoroughly made, then primed with white lead, the nails being all sunk, then puttied, then sand-

papered, and then painted with the white lead. They are on stands 11 inches from the ground. He would not have his hives on the ground, nor would he have them on tight stands, but wants them so that the cats and chickens can get under them, and so that there will be free circulation underneath. In this way the hives keep dry, the bees are healthy, and there are no ants or mice to bother.

The day that the picture was taken there was a fierce fire raging just at the left of his place, and his wife and youngest son were badly frightened, and were watching the fire, so that is the reason they do not appear in the picture. Two of his houses were within 30 feet of the fire, but no damage was done to his property.

MR. J. H. HONGKINS, of Winnebago Co., Ill., writes us that he thinks he is about the oldest subscriber to the American Bee Journal, as he has taken it continually ever since its first editor, Samuel Wagner, began to publish it in 1861. He has never missed receiving one number in all those years, and he has preserved nearly every copy.

We suppose there are not very many of our subscribers who have such a record as Mr. Hodzkins can show.

UNTESTED

Italian Queens Free

BY RETURN MAIL.

For sending us **One New Subscriber** for one year, to the American Bee Journal, with \$1.00, we will send, by **return mail**, a fine **Untested Italian Queen free** as a premium. This offer

is made only to our present regular subscribers.

We will mail one of the above queens alone for 75 cents; or 3 for \$2.10.

Please do not conflict the above offer with the one on another page which refers to Red Clover Queens. For sending us **two** new subscribers, and \$2.00, we will mail free as a premium an **Untested Red Clover Italian Queen**.

144 & 146 Erie St.,

CHICAGO, ILL.

After all this is said in favor of foundation in the brood-nest, it should be added that there are good authorities who think it economy to use for a swarm nothing but starters for the first half of the frames. If lived on these there will be very little, possibly no drone-comb built, the building of drone-comb commencing after the first half of the hive is filled. To prevent the building of drone-comb in this second, half, full sheets of foundation are given *after* the first half are filled.

Convention Proceedings.

(Continued from page 38.)

Report of the Minnesota Bee-Keepers' Convention.

BY DR. L. D. LEONARD.

THIRD DAY—FORENOON SESSION.

The first thing on the program was a paper by George A. Forgeson, on

MIGRATORY BEE-KEEPING.

Migratory bee-keeping with me was a child of necessity. Living as I do about two miles from any timber, and that timber mostly oak, my only honey-flow was from white clover, and that was by no means certain.

So reading one day about migratory bee-keeping set me to thinking and figuring. My figures ran about as follows: 10 colonies 20 days on white clover—50 pounds per colony; then load them on the wagon and move them six miles to the basswood flow, there to remain 25 or 30 days—50 pounds per colony more; then load up again, and in the silent hours of the night drive 20 miles east to the buckwheat fields, there to remain from 35 to 40 days—an easy 100 pounds more. Result, 200 pounds per colony; 100 colonies, 20,000 pounds, to be sold at 10 cents per pound. The figures ran away with me, some of them got lost, and I have not yet found them. Like hatching chickens by steam, it figures up nicely on paper.

But, alas! after three years of migratory bee-keeping I awoke to find that my dream of wealth had not been realized. The move to the basswood never paid for the trouble; the move to the buckwheat fields was better, as, for instance, the first year from 10 colonies I extracted 1385 pounds of honey in 35 days, leaving sufficient stores for winter. Although I did not do as well the next two years, it led me to establish an out apiary at Hastings, where I have had paying crops for the past three years.

(GEORGE A. FORGESON.)

This paper was followed by one written by Mr. Wm. Russell, as follows, on

PREMIUMS AT OUR STATE FAIR.

It is generally understood that the principal objects aimed at by the Minnesota State Agricultural Society are largely educational in their character—the bringing together of all that is best and most fully developed in each particular line of agriculture in this and adjoining States. Those who have attended the State Fair for a number of years can not fail to be impressed with the improvements that are apparent in every department, and if they are at all observant they will carry away with them some ideas that will be of use in the particular line in which they are engaged.

It is from the standpoint of a bee-keeper, however, that I would like to say a few words to those assembled here. I am looking back to my first visit to the Fair, and also to my first exhibit, and comparing them with the Fair of 1900. I can see a vast gain for the better. It is true that some of the old familiar faces are not to be seen any more, having laid down the burdens and pleasures of bee-keeping, to be taken up by younger, if less experienced, hands. Not being a farmer, I suppose almost any one can grow good potatoes, cabbage, onions, and all that sort of things, if he has good land to begin with, but I need hardly tell this audience that the inability to produce a really first-class article of comb honey is something of which no one need be ashamed, for it requires more skill than the average bee-keeper is possessed of, judging by the specimens that one sees offered in the honey market. I think quite a number of those present will bear me out in saying that there is a material improvement in this line on honey seen at the Fair, and it is to be hoped that, as in the past so in the future, bee-keepers will vie with each other to produce only a first-class article of both comb and extracted honey, and that their best efforts will always be directed to making a more creditable exhibit at the next Fair than at the previous one.

One of the most important features of these exhibits is the opportunity offered us of measuring ourselves with our fellow exhibitors, and thus enabling us to decide pretty accurately just what ground we occupy as honey-producers and successful exhibitors.

Another feature of the Fair, and one not to be overlooked, is the premium list. I find by referring to the premium list for 1900 that the sum of \$281 divided into 79 premiums, comprises the list which is composed of 23 lots, beginning with the "most attractive and finest display of comb honey," and ending with the "grand sweepstakes," which means the most attractive exhibition in this department, all things considered.

In order to understand this matter properly it is necessary to compare the Minnesota list with one or two others, who shows, by the way, do not come up to that of Minnesota by any means, for instance:

	Minnesota.	Illinois.	Wisconsin.
Finest display of Comb Honey	\$12-8-5-3-28	\$20-15-5-40	\$8-4-12
Finest display of Extra'd "	12-8-5-3-28	20-15-10-45	6-3-9
Granulated Honey	5-3-1-9	20-15-10-45	
Bee-wax	5-3-2-1-11	12-8-4-24	2-1-3
Honey-Vinegar	3-2-1-6	4-3-1-8	
Extracting-Frames	5-3-1-9	5-3-3-10	
Nucleus of Yellow Bees	3-2-1-6	4-3-2-9	8-4-12
Nucleus of Dark Bees	3-2-1-6	4-3-2-9	
Carniolan Bees		4-3-2-9	8-4-12
Total for bees	12	27	24

It will be seen from the foregoing that in some particulars our premiums are considerably behind those of Illinois, while they compare favorably with those of Wisconsin. For instance, Minnesota pays a total of \$12, divided into six premiums, for bees, while Illinois pays a total of \$27, and Wisconsin a total of \$24, divided into four premiums. It is to this part of the premium list that I would like to call special attention. It is a well-known fact that a person can always get just about what he is willing to pay for, and this holds as good in exhibiting bees as in other walks of life. I will venture the assertion that there is not a bee-keeper present that would care to take a choice queen with a nucleus of her bees, and shut them in an observatory hive for a week in an overheated room like that at the State Fair, for a premium averaging from \$3 to nothing. It simply will not pay, and that accounts for the poor showing made at the Fair of 1900, and I consider the remark of the judges that it was the poorest lot of bees they had ever seen, was perfectly justifiable. Were the same policy pursued with other kinds of stock the result would undoubtedly be the same in a very short time.

I hope that anything said in this paper will not be regarded as a complaint against the premium list or any one connected with the management of the Fair, for it is not so intended. In the main, the premiums are liberal, that is, while only a few bee-keepers make exhibits, but suppose 50 should decide to make exhibits, then there would not be enough to pay the expenses of half of them. Should we ever be blessed again with a good honey-crop and a pushing assistant superintendent, it is safe to say that 50 entries would be secured. While our present assistant superintendent holds office I can assure you that there will be but very few bee-keepers in the State that will not have an invitation to attend the State Fair.

The Fair has been quite a success, its finances are steadily increasing, and it seems to me that the time has come for this Association to take some steps to secure more money for the premium list. It is not my intention to say just what should or should not be done in that line. My main object in writing this paper is to outline a few of the more important features of the premium list where they might be amended, in order to start discussion; for I consider that unless the reading of a paper does that it fails entirely in its purpose, for "In a multitude of counselors there is safety."

WM. RUSSELL.

Following this paper was one by Dr. E. K. Jaques, on "Bee-Keeping for Pleasure."

The election of officers for the ensuing year resulted as follows:

President, Wm. Russell; first vice-president, G. A. Forgeson; second vice-president, G. H. Pond; third vice-president, Dr. Mary McCoy; secretary, Dr. L. D. Leonard, Syndicate Block, Minneapolis; and treasurer, L. E. Day, Executive committee, H. G. Acklin, Wm. VanVleet, E. K. Jaques, L. D. LEONARD, Sec.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Contributed Articles.

Thick vs. Thin Brood-Frame Top-Bars.

BY S. T. PETTIT.

I WOULD like to reply to Dr. Miller and Editor Root, who seem to be not a little excited over my article on top-bars (see *Gleanings in Bee-Culture*, pages 227 and 380.) In the first note the editor says, "We first tried top-bars that were wide and only $\frac{1}{4}$ -inch thick. We had trouble from such bars sagging, and the building of burr and brace combs." In reply I wish to say, had these $\frac{1}{4}$ -inch thick and 9.8 wide top-bars been kept straight by some means, they would have remained as clean as the cleanest the editor ever looked upon. I haven't the shade of a doubt about it.

I can not understand how it possibly can be that the editor's experience shows him that brace-combs are more plentiful with the use of top-bars $\frac{3}{8}$ -inch thick than with $\frac{7}{8}$ -inch thick. Can it be that the length of the Langstroth top-bar allows it to sag when only $\frac{3}{8}$ -inch thick? With all due respect to the editor, I firmly believe he is mistaken in that. My experience with $\frac{3}{8}$ -inch top-bars covers a period of 15 or 16 years, and it is altogether different from his. I have made many tests with the different kinds, so it is not theory but long experience from which I speak.

On page 380, Dr. Miller says, "His strong point is that, by having $\frac{1}{4}$ -inch more depth, the space of 1000 to 2000 cells is lost." Yes, that is my strong point, which I will take further notice of later.

No, I did not make the mistake of reckoning that the same number of bees were occupied brooding those sticks as would be occupied in brooding $\frac{1}{4}$ -inch depth of comb. I neither thought it, nor said it, but this is what I did say, "The saving of that space in each hive is a matter worthy our best consideration." I think most bee-keepers will agree that 1000 to 2000 cells in a hive are of more value than useless lumber, adding weight and unnecessary expense. I hope after due consideration the Doctor will agree with this also.

Then the Doctor proceeds to use about half a column, and proves nothing, except that he "don't know" what he is talking about—it's all wasted energy. Further on he says, "So if the prevention of burr-combs by deep top-bars be all a delusion (which I do not believe)"—well, I suppose I can show the reason why he does not believe it. He did not make personal, practical experiments for himself and for the benefit of the public for whom he writes; but—well, perhaps I can do no better than to give the words of Editor Root, as follows:

"Dr. Miller was greatly struck with the idea, and after some extended correspondence with the Doctor we decided that we would launch forth, for the ensuing year, the new top-bar."

Then later he said that he and Dr. Miller had evolved the new top-bar, by revolving around each other by the coat-tail—a clear case of *conviction and prejudice* not founded upon personal, practical experience, hence the Doctor's complaint "which I do not believe."

I quote from a letter sent me from the U. S. A., dated April 4, 1901: "I have read with much interest your article in *Gleanings* for March 15, and want to say that I endorse all you say in regard to *wide and thin* top-bars; and bottom-bars $\frac{3}{4}$ -inch wide. For a number of years I have been using a top-bar $\frac{1}{4}$ -inch thick, and $1\frac{1}{8}$ -inch wide, and not a burr-comb on a single frame in 8 years' use." I may add that a few days ago Mr. Cruikshank, who takes *Gleanings*, and lives near me, called upon me, and in alluding to this discussion said: "I use $\frac{3}{8}$ -inch thick top-bars, and have no bother with burr or brace combs."

But Doctor Miller says, "I still want the $\frac{7}{8}$ top-bars for the sake of having the sections so far from the brood-combs that the bees will not find it convenient to carry up a lot of black wax to spoil the snow-white sections." This statement reveals the fact that the Doctor has not yet learned all the valuable uses to which the queen-bar or perforated metal queen-excluder may be put. My practice is to get the sections just as close to the brood as I can, preserving all the necessary bee-spaces. To this end I want thin top-bars. Then, to prevent the bees from moving up

dark wax, and to bar the drones with their filthy habits, and the queen from the sections, and to restrain pollen, I use a queen-bar, or, if you please, an all-metal perforated zinc queen-excluder, which has a $\frac{1}{4}$ -inch thick rim and two cross-pieces. This arrangement gives the same distance between the top-bars and sections as he wants, with all the advantages enumerated. But I would bring the sections closer down if I could and did not dispense with the queen-bar.

On page 380, Editor Root says, "It seems to me that Mr. Pettit assumes, or indirectly assumes, that those 1000 to 2000 cells are lost because of the brood that might have been reared in them." Exactly so, and that is what hurts. Continuing, he says, "but it is very seldom that brood is reared any closer than within an inch of the top-bar, with ordinary Langstroth frames." If that be so then the management is faulty; yes, very bad. Let me explain by giving my practice:

All colonies, whether weak or strong, are kept warm by a warm cushion over each. Then when the early flow sets in, a super filled with comb is given to all the strong colonies, with that warm cushion on top, and a queen-bar to keep the queen down. Then the surplus honey will go into the super, and the brood and pollen will generally fill every cell to the top-bar, and of course the thinner the top-bar the less the burr-combs and the more the brood. While the weather is cool a few cells along the top-bar, especially when the bees are not in the best condition, will contain unsealed honey and pollen; but as the heat increases brood will come to the top-bars. About 25 or 26 years ago I commenced to use a cushion on top of my hives, and when the comb or extracting super goes on, the cushion goes up. It stays right on, summer and winter.

Mr. Root is just now finding out the benefits of a warm cushion, and so will it be with the thin top-bar; but I hope it will not take a quarter of a century. Ontario, Canada.

Cross Bees at Swarming-Time, Etc.

BY WM. M. WHITNEY.

SOME one asks why bees are sometimes cross when swarming. Tell him to examine the hive they came from, and if he finds little or no honey, the question is easily answered. Who wouldn't be cross, crowded out of home with the whole family in a starving condition? Or, possibly the swarm has been clustered a long time. Pull one of the crossnest ones in two, and see how little honey it has in the honey-sac. If they have plenty of honey, they are gentle as kittens—wouldn't sting if they could, and couldn't if they would.

INTRODUCING QUEENS.

The communication on page 311, entitled, "Introducing a Queen-Bee," etc., is really amusing. The gist of the whole article seems to be a *posteriori* attempt to show that the honey-bee is actuated by pure, unadulterated selfishness. Now, it occurs to me, that, taking the effects indicated in the communication as causes, and reasoning *a priori*, it would not be a difficult matter to show that the honey-bee is prompted by the highest type of love and patriotism. A colony of bees is very much, in many respects, like a community of individuals, in which individual rights and privileges must be held secondary and subject to the well-being of the body collectively.

Among enlightened and Christian people, places of comfort are provided for the unfortunate and infirm; but, the time was when such persons—whether their condition was the result of heredity, accident, or old age—were disposed of in the most convenient manner possible, as thought for the good of the majority. In fact, we occasionally hear the thought expressed that such might still be a good practice.

The community of bees, either by instinct—if any one can tell what that means—or by some other power, seem to know when any member among them has ceased to be of use to the body as a whole, and take the only possible means to perpetuate the existence of the colony. Why, how long do you suppose a colony of bees would live, were it to provide an asylum to illustrate the idea—in the several corners of the hive, with nurses to care for the worse than worthless drones, the dear old mother-queens, and the ever faithful, but weak and worn-out workers? Does it show a want of love, to do the only possible thing necessary to preserve an existence? How persistently the little heroines defend their hearthstone against all intruders, even to the sacrifice of life itself. How carefully they

nurse and care for the young, from the egg to the emerging of the young bee, which is to perpetuate the existence of the family in the same manner in which they are doing it. Do not these acts imply the highest type of love and patriotism?

But this is sufficient to serve the purpose intended; hence, I will not pursue the subject further than to add, that probably neither position is wholly tenable, but that the whole matter is governed by a principle, or law in Nature, or evolution, if you please, which simply, in a sense, means the "survival of the fittest."

One can scarcely refrain from admiration of the gracefulness of that stately old queen, as she makes her debut into the residence of total strangers, and is so graciously accepted, and immediately crowned sovereign of the realm. Yet, it is a little surprising to think it necessary to use a *little smoke* just at the right time. It tends to divert the attention; to pervert the sense of smell; to set the whole colony to gorging themselves with honey, of course, and, possibly, may have something to do in helping them to form an opinion of the graciousness of her statelyness. However that may be, try introducing this same old stately queen into a queenless colony that has queen-cells forming, however imperfect they may be, and note how little impression her stately figure and graceful movements make upon the occupants of the hive. Try the same experiment with a colony having the worst of all pests—laying-workers—and note what will become of that magnificent old queen in about a minute and a half.

My! But enough. Allow me to say, in passing, to beginners: Don't try any such experiments with your *\$200 long-tongued red clover queens*. If you do, you will have your disappointment and misfortune to remember as long as you live. Yes, this reminds me, that there seems to have been raised, simultaneously, all over this country, during the last year, an immense number of *long-tongued queens*. When I think of it, it seems surprising—but, then, I don't know as it is either. My bees have always gathered nectar from red clover. Now let nobody build hopes high that he can get a \$200 queen from me for 50 cents. I have none for sale.

My belief is, that such honey is of very little value except possibly for brood-rearing. When a boy, as I got it from the bumble-bees nest, while it was sweet, it was very watery, and not specially of fine flavor. I believe in letting the bumble-bee monopolize the red clover honey business.

Kankakee Co., Ill.

Circulation and Respiration in Insects.

BY PROF. A. J. COOK.

RESPIRATION and circulation, or the securing of oxygen and elimination of waste, and the conveying of elements from one part of the body to another, are exceedingly important functions in all the highest among animals—so important that we denominate the cessation of these functions as death. A chicken in Michigan lived for weeks with its head cut off. That part of the brain—the medulla oblongata—which is the centre of breathing, remained intact, and so the chicken continued to breathe, and the heart ceased not to beat, and so the chicken lived. Of course, it could do no thinking, nor could it walk; but so long as breathing and the circulation of the blood continued, we say the chicken lived.

In insects, and so in bees, respiration loses none of its importance; but because of its peculiar character, the circulation of the blood becomes much less complicated. Indeed, we may say that the respiratory system is inversely proportional in its complication, to the circulatory apparatus.

In us, as with nearly all vertebrate animals, breathing is specialized, and restricted to narrow limits. The lungs are the organs, and in mammals the thorax is their seat of action. These limitations make a very complete circulatory apparatus very necessary, and so we have the great force-pump the heart—the conductors leading from it, the strong arteries; the minute capillaries which unite arteries to veins, and which serve to bring the blood close alongside the tissues; and the veins, the great conduits, that return the blood again to the heart. The oxygen, which is really the most important food, if we may so designate it, is only received in any considerable quantities by the lungs; (the skin respires in a small way, and so we get a modicum of oxygen through skin respiration) the blood then must have two circuits—the one to the lungs to get this vitalizing oxy-

gen, the other to the body to give this same oxygen to the tissues. Equally important is circulation, in bearing the waste from the tissues, and equally important are the lungs in separating this waste—the ashes of work, if we may so speak—from the blood. In all these higher animals the air comes to the lungs in a single tube—trachea—and enters this either from mouth or nose through a single aperture—the glottis.

When we come to insects, we find a very different arrangement. The bee and all insects must have the oxygen, and if very active, as are bees and all other insects of their order, they must have a large amount of this vitalizing element, the most important food-product. The insect's breathing-organs are not localized; they are everywhere in the body. Nor does the air enter at the opening, but rather from several breathing-mouths, situated in pairs along the sides of the body. These spiracles, as the breathing-mouths are termed, are doubly guarded, first by hairs, and also by membranous valves, so no dust is likely to gain access to the insect lungs, or, in other words, to the intricate breathing-tubes. These breathing-tubes, or trachea, as they are called, branch and rebranch, so everywhere in the body we find them. Thus the life-giving oxygen goes everywhere in the body, and there is no need of a complex system to circulate it.

These trachea are curious in their make-up. They are made of spiral threads, lined with an epithelial or cellular membrane, as are our own bronchial-tubes. Thus the ultimate structure of the insect lungs is not essentially different from that in higher animals. In both cases we have an intricate and extensive ramification of tubules, lined with a cellular membrane. The spiral thread which forms the tubules in the insect respiratory system, is in appearance and construction, as if we should wind a fine wire closely about a lead-pencil, and then remove the pencil without disturbing the wire. We note, then, that the insect's requirements are met in that air, or rather oxygen, is carried everywhere to the tissues.

The circulatory apparatus, then, need not be very complex or energetic. It has not to carry the all-important oxygen. Thus we understand why the insect blood is not red. Blood is red because of a coloring element called haemoglobin. This is large in amount, which shows its importance. It is emphasized as we know its function, and it is to carry oxygen. In insects there is no need to carry oxygen, as the air with its oxygen goes everywhere.

We understand, then, why insects have no red blood. Were it there, it would be like Othello in the play—its occupation would be gone. The only organ of circulation in insects is the heart. This is dorsal, and lies close along the back. The blood in this always passes from behind forward. Valvular openings along the side permit the blood to enter. The heart contracts and sends this blood-stream forward. It is emptied near the head end of the central opening—the *aorta*, as it is called. There are no specialized vessels to carry it back. It crowds along between the visceral organs, and rushes into the tubular heart, to be driven again towards the head. This heart action is to keep the blood stirring, so that as active tissues take out the nourishment, no portion may be depleted of nutritive elements. All is constantly being mixed. And so all the blood is kept as rich as any of it. Thus we see how an intricate or elaborate air-system makes unnecessary a complex circulatory apparatus. The machinery in all organic nature is always simple, unless there is call for something intricate.

Los Angeles Co., Calif.

Scientific Breeding as Applied to Bees.

BY ARTHUR C. MILLER.

IN an editorial on page 355, reference was made to an article of mine entitled "Scientific Breeding," and just criticism was made of my expression, "Do not confuse in-breeding with in-and-in-breeding." When writing that article I had in mind *in-and-in-breeding* as that term is commonly understood, and I ought so to have expressed it. It is commonly understood to mean the promiscuous breeding together of animals closely related, and as the results of this in ignorant or careless hands is generally disastrous, it is supposed to prove that the breeding together of such relations is disastrous *per se*. On the contrary, it is the chief reliance of the skilled breeder for intensifying desirable tendencies.

The article was not intended to be an essay on thorough breeding, but was intended to do exactly what it has done,

i. e., call attention to the then present status of the subject, and arouse interest, comment and study. The breeding of stock in such a way as to develop and establish desirable traits, or, in a word, thorough breeding, is a subject on which many volumes have been written, and to endeavor to give any satisfactory exposition of it in the space available for an article in our bee-papers is impossible. The best we can do is to call attention to the subject, refer those interested to the standard works on it, later discuss salient points, and study it as applied to bees. We shall certainly meet some variations of the laws applied to higher animals, for with bees the drone does not represent two lines of blood, as does the queen, and other factors are also different and will require much study and research.

I believe the breeding of queens is passing into the hands of a comparatively few persons, and these well educated and skilled in the art. It is for the best good of all concerned that it should be so, and Mr. Martin's plan is in this direction. For a time it may cause some personal distress and necessity for readjustment by those who have to drop the business, but bee-keeping will be benefitted thereby. It is only the working out of the natural laws of specialization and the survival of the fittest. Those who kick against it will only show their ignorance of great fundamental truths.

The exact details under which the system will be conducted are properly a subject for debate, and the more full the discussion the more readily will the change be made. The average honey-producer is certainly not in a position to study into the traits of individual colonies, nor when he observes desirable characteristics has he the time or skill to develop them. But if he can turn that queen over to the queen-rearer with a statement of all the observed traits, and of the pedigree so far as known, then is she placed where the man with the time and training can observe, and act on his observations. Suppose each of twenty skilled producers were every season turning over to the queen-specialist his best queen, would he not then be in a position where, even if not able to control the drones, he could produce queens far beyond anything we now have? The skilled queen-breeder of to-day need not fear this plan, for if he is worthy to survive he will quickly find his place as a queen-specialist. Rambler's plan is entitled to our serious consideration.

Providence Co., R. I.

No. 7.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

(Continued from page 376.)

"NOW, Mr. Bond," I continued, "if you will please come a little closer I will show you how I take a super off the brood-chamber."

Mr. Bond took two or three rather timid steps away from the apple-tree, against which he had been leaning while I was explaining things, and then halted when he saw me using my old chisel at one end of the super to loosen it from the frames.

"O, come along!" I called, when a side glance showed me his action. "These bees are as tame as kittens now. They'll make no sign of a fight while they are full of honey, you know. Don't forget that, Mr. Bond. And, let me remind you, also, don't forget that you are wearing the best kind of a bee-veil, and are at liberty to keep your hands in your pockets, if you prefer to do so."

"As I was saying this I had reached the last frame in my prying operation, and, as that frame stuck to the super worse than any of the others, it came loose with a snap and a bang, the usual result with which all practical bee-men are familiar—following so quickly that I hastily reached for my smoker, standing near by. A few puffs of smoke, only, were required to drive the out-rushing bees back. My quick movement in reaching for the smoker must have looked to Mr. Bond like the effect of sudden fright, for he uttered a hearty guffaw, and then said, banteringly:

"Say, Mr. Gehring, how long will bees stay tame after you've made them gorge themselves on honey? Those in that hive act as if they hadn't had a lick of honey to eat to-day. Do you know that it is now 4 o'clock? and that it wasn't quite 2 o'clock when you left them to tend to that swarm?"

Mr. Bond was right. But I wasn't quite willing to acknowledge that I had made a mistake by forgetting the point he made. I, therefore, attempted no direct reply to his bantering questions, but said:

"I'll show you in a few minutes, Mr. Bond, that these bees will behave all right when they have become satisfied that no harm is being done to them. If you'll come here and take this smoker while I take the super off, it will be a good lesson for you for future use."

Mr. Bond did as requested, and I continued: "Now, when I lift the super the bees may make another rush. If they do, just blow a few gentle puffs of smoke over the top of the frames—that will send them back. But if they make no rush, nor act 'fidgetish,' don't use the smoker on them."

With a steady, even motion I raised the super clear of the frames, and carefully deposited it on a near-by heap, keeping a watchful eye, meanwhile, on the hive, and on Mr. Bond in particular: for I could not be certain what either the bees or the man with the smoker might, or might not, do. A few of the bees, either from the hive or from the bottom of the super, of course took wing, but made no vicious demonstration. Mr. Bond, however, did not know how to interpret the actions of bees, hence he did not waste a moment's time in watching to see what these flying bees would do. Before I had time to turn, after setting the super down, he was pumping the smoker with frantic energy, and sending dense volumes of smoke down between the frames of the open hive.

"Quit that, Mr. Bond!" I cried—not taking time to be polite. "Stop that smoke! Don't you see the bees are not doing any harm? Never use the smoker unless it is absolutely necessary! Remember that, now and always, Mr. Bond. It has a demoralizing effect on them, and makes them harder to handle, because smoke-treatment like that frightens and irritates them. You can see that for yourself," I concluded, pointing, as I approached the hive, to the bee entrance where the poor, confused little things were pouring forth, in a frantic rush to escape the smoke.

"I beg pardon if I didn't do the right thing at the right time," meekly replied Mr. Bond, as he handed the instrument of possible torture to me. "But, you see, these practical lessons you're giving me are hard on the nerves—my nerves, I mean."

"That surprises me, Mr. Bond," I replied. "I always had a sort of an idea that 'fair-fat-and-forty' people, like yourself, carried their nerves out of sight and out of reach of attack from any source. But let that pass, Mr. Bond. The lesson is the important thing to consider, hence I am not at all sorry that you have had a part in this 'little fracas'—as, I believe, you would call it—because you'll be less liable to forget it."

"Do you mean the fracas, or the lesson?" queried Mr. Bond, mischievously. "I mean the lesson suggested by the fracas, Mr. Bond," I replied. "The main point of interest in the lesson is, the use and abuse of smoke in the apary. Owing to the unintentional abuse—or misuse—of smoke in this particular instance two undesirable effects, to put it mildly, were the direct and indirect result, thus:

"Your furious bombardment with a bee-smoker disturbed and excited a whole colony of otherwise docile bees. That was the direct effect. The indirect effect of it was, or is, that your lesson will have to be postponed for to-day. It is now too late in the day to keep the hive open longer for the purpose of demonstrating this part of the lesson. Besides, it would not be wise, or even merciful toward the bees, to trouble them further while they are unduly excited.

"You needn't keep your veil on any longer now, Mr. Bond. There is no danger at all after I get this super back on the hive," I said, as I was replacing the super, and then closed the hive.

"That means, then, that school's out and I'm dismissed. Is that?"

"Not exactly dismissed, Mr. Bond," I replied; "for I want you to come again as soon as you can, on a bright, warm day. Remember to come as early as seven in the morning, when you do come."

"By the way, Mr. Bond, lest I forget to ask you: Do you take the American Bee Journal? I name that, in particular, because I read it in preference to any of the other bee-papers, and because I think it's the best in most respects; though others, as far as I know them, are good, too. The fact is, bee-papers are somewhat like bee-men—they're all good—some more, and some less."

We were walking toward the honey-house as I talked. On the way Mr. Bond removed the bee-veil and carried it in his hand until we had reached my work-room. I requested him to take a seat, but before doing so he handed me the veil, and then said:

"If you had asked me that question about the Bee Journal the first thing this morning, I would have seen no reason for hesitating to tell the truth about it. But after

the experience I have had to-day, and the lesson I've had in practical bee-keeping, I'm ashamed to confess that I have never taken the American Bee Journal as a regular subscriber. The fact is—and perhaps I ought to be ashamed of that, too—I've never before felt, as I now do, that I needed a bee-paper of any kind. My good old father never took any, and he got along very well with his bees—that is, I always thought so before to-day.

"You have done no worse in that," I replied, "than hundreds of others are doing all the time, without ever feeling a pang of guilt, or showing the least sign of repentance. And most of them are otherwise good and sensible men and women, too, Mr. Bond. The Missouri gentleman I told you about was one of that class of bee-keepers. He sneered at the very idea, when I asked him that same question I've just put to you. But you know what he lost by being wise in his own conceit, if you haven't forgotten what I told you about his bee-business transactions with me. Why, Mr. Bond, that man actually laughed at me when I tried to convince him, one day, that bees have eyes and could see as well as he or I could. To prove that I was wrong he stepped before the bee-entrance of one of his hives and said:

"Now, don't you see how these bees run against me as they go and come? Would they do that if they could see me?" he asked triumphantly.

"Couldn't you convince him that he was wrong? Or didn't you want to?" Mr. Bond asked.

"My friend," I replied, "I didn't even try to do that, because I knew that a man who refused to take a bee-paper, not because he couldn't afford it—that's often a valid excuse—but because bee-papers couldn't teach him anything, was too far gone in conceit to be cured, either by argument or actual demonstration.

"No, Mr. Bond," I concluded, "it never pays to try to get along successfully in the bee-business, on a large or on a very small scale, without a bee-book to begin with, and a bee-paper to continue on."

(To be continued.)

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editor.)

Exchanging Old Colonies With Nuclei.

I had a mind to form nuclei from a colony that swarmed a week ago. Rather than to destroy queen-cells I thought to form nuclei with them. Then to remove other hives and place these nuclei in their places, but a friend told me if I did, the returning bees would be likely to kill the bees and destroy the queen-cells. Would that likely be the result? On going through it to-day I found one queen, but three or four cells, and they all empty, so I could not have carried out my project had I wished. It appears I got that idea from Gleanings in Bee-Culture, but haven't it to refer to now. Iowa.

ANSWER.—Put a nucleus with a young queen in place of a strong colony, and there is danger that the queen may be killed, but I think it would not be likely that a queen-cell would be disturbed by the returning bees.

Effect of Too Many Stings—May Have to Abandon Bee-Keeping.

I have been keeping bees three seasons, and had many stings. The spring of 1900 I was troubled with burning and itching for about two months. I thought no more about it, but last March I received quite a lot of stings on the head and face, and now I am troubled terribly with itching, burning, and breaking out over the body as well. The doctors here say it is some kind of poison. I am 65 years old. What is my trouble?

I visited relatives in east Virginia three years ago, who have many bees. I had rheumatism badly, and they assured me if I would get bees, and work with them, and receive stings freely, the formic acid would certainly cure

me; and to my hope I do not have any rheumatism now. I have frequently thought if Dr. Miller would caution beginners against too much bee-poison, it would have benefited me.

Let me add that I at first rather encouraged stings. Now I am seeking a remedy to eradicate the poison. I am reasonably sure that my blood is heavily charged with bee-sting acid. I think Prof. Cook doesn't claim it to be formic acid. KENTUCKY.

ANSWER.—Your case is a very exceptional one, and it is among the possibilities that you may never be able to work with bees without suffering too much inconvenience. No remedy, however, will be needed for the stings received in the past. It is not supposed that the poison remains in the system, and all you need to do is to avoid stings in the future. It is also possible that in time you may become habituated to the stings so as to be able to continue working with bees. It will certainly be well for the present to take some care not to have too many stings, at least until you find that no serious effects result. If you find no abatement with time, but every sting bringing just as much suffering as ever, then your only course is to give up bee-keeping entirely.

Management for Increase.

As I am trying the Newman plan of increase it hardly suits me, as he says to put the queen-cells on a new stand. I wonder if that is what he meant, or is it a mistake in the print? He says remove the frame on which you find the queen and three other frames of brood, and put into a new hive on the old stand, removing the old hive to a new stand, then put in a queen-cell 24 hours later. Don't you think that would depopulate the old colony so there would be danger of the cell getting chilled? WISCONSIN.

ANSWER.—There might be some danger in the direction you indicate. Do this: Put the queen with half the contents of the hive on a new stand, and a day or two later let the two hives swap places, giving a cell to the queenless part. In that case, as you put the queen on the new stand, enough bees for safety will remain with her, and by the time you make the exchange some of the bees will have marked the new location so as to return from the field to it, and the part without the queen will have learned their queenlessness by the time the exchange is made, so that there will be no danger of their deserting the brood.

Feed for Weak Colonies—Foul-Brood Question.

1. Is there a good substitute for honey with which to feed weak colonies? If so, what?
2. In what way does foul brood manifest itself? There are young bees lying on the outside of some of my hives. They are still white, and do not have their wings formed yet. PENNSYLVANIA.

ANSWERS.—1. Granulated sugar with water, or a syrup therefrom, is probably the best. In the spring, after bees are flying daily, almost any sweet that bees will take can be used.

2. It is hardly the place to give here all about foul brood. Consult your text-book on bees. But you need not fear foul brood because young bees still white are lying outside the hive. If there are only a few, it may be the work of wax-moths. More likely, especially if there are many of them, the trouble is starvation. In that case, you will find some of the skins carried out with the insides sucked out.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

EARLY QUEEN-REARING IN THE NORTH.

Swarthmore, you're a "clever chiel," but, all the same, queens in the North are not going to be reared for sale six or eight weeks ahead of natural season. The weather (we have all found this a phenomenally backward spring) is a fearful antagonist to buck against. Why, this spring seeds planted in pots in the window, inside the house, refused to come up. I suspect you would have had some fun making your colonies rear many drones in March. I can readily believe that drone-eggs would mostly get through the mails all right—except when subjected to freezing. If I remember aright, those who have tried to destroy drone-eggs and drone-brood, without destroying the combs also, have found it a very difficult thing to do. But we'll give you a good, long credit-mark for your experiments and success. A queen-breeder might think it worth his while to gain a much more moderate time than six weeks. And the amateur breeder might wish drone-eggs from afar to cross stock on hand. Page 307.

THIN BOARDS AND SECTIONS FOR KEEPING HIVE-RECORD.

Mr. Davenport's thin boards, 4x18, make excellent records, no doubt; and "sponging them off" with a *plane*, when the record is no longer needed, is simple and effective. I use for this purpose the broad side of a section—carry one or several in my pocket—and renew the surface on occasion by shaving it with my pocket-knife. Either his way or mine is excellent to preserve things which are eventually to be put down in a book. Quite inconvenient to be running to a book to write as often as a poor memory demands. Say, dear reader, don't you need a wooden pocket-book? There's lots of "money in it." Page 309.

APPLE-BLOSSOM HONEY.

Allen Latham's way (page 310) is all right to get choice tit-bits for home table. Hardly do to amplify it so as to boom the main harvest that way. A section two-thirds from apple-nectar and one-third sugar-honey would be still more exquisite than apple-honey pure and simple. Apple-honey inclines to have a little too much flavor. He's right that it is delicious the day it is brought in; but I would hardly agree that it is the only nectar good at once. He must have forgotten the basswood. Probably no nectar whatever is fit to *keep* if extracted when only one day old.

FEEDING BEES IN A TOPLESS WIRE ENCLOSURE.

If it is really true that all that is needed to feed any colony in the open air is a wire fence around it six feet high (top all open to the sky), we certainly ought to know it. Very unique and remarkable gun for our arsenal. But let's not tell our brothers that it never kicks till we have fired it off several times with our own bees quickly learned the way out and in; and it strained my believing "machinery" to believe that robbers would not learn the same. But the more I think of it the more I relent; and the bent machinery revolves a little slowly in a jiggle-joggle sort of way. If it does work as stated, at all times, and in other people's hands, the more credit to you. Page 310.

RIDDLE.

A living machine without a heart,
With no tender throbs in any part,
Of iron rules a slave, I ween,
It hews at the throne of King Routine;
It's born of the crowd, and dies alone,
And spares no life, not even its own.

I think it probable that W. W. McNeal is right in claiming that the bee is entirely destitute of love for any other living thing. It has lots of love of country to atone for its lack of personal affection. But when he comes to speak of the bee's *reasons* for action he gets woefully beyond his depth, it seems to me—as most of us do. In consciousness and mode of mind action, living creatures differ much one from the other; and all differ, almost immeasurably, from the human creature's way of thinking and feeling and intuition. A squirrel is conscious that a surplus of food can be turned to future good account. Many other animals will wantonly destroy their

own food (all but a few mouthfuls immediately in front of their eyes) even with starvation as the very next thing on the books. A swine likes a clean bed, and is conscious of the personal rules required to keep it so. A cow equally likes a clean bed, yet with disgusting unconsciousness defiles it and everything else in the vicinity. A man sees a fellow man with a crushed limb, and is conscious of his pain—to such an extent often as to be obliged to turn away his eyes. A bee sees a fellow bee half crushed, and in all probability has not the slightest idea that there is any pain involved at all. If I am right, it is only in few and rare instances that a few of the most intelligent of creatures have shown any comprehension either of death or of silent suffering. Many creatures seem to be able to comprehend *cries* of pain. Even the apathetic bee is still a little in doubt on that point. Among swine an angry attempt to *silence the cries* takes the place which should belong to intelligent pity. As to the bees blaming the queen for her sudden disappearance when caged, and remembering it against her to punish her when she comes back, I fear that is getting into a pretty high grade of comedy. But say, in this matter of assuming that bees look from a human stand-point, don't you go to looking my writings over to see how many cases of it you can find! Page 311.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

CLAREMONT A MODEL CITY.

We have a very exceptional society here in Claremont. The motto of our college is, "Our Tribute to Christian Civilization." The unwritten law of the college is, "No Tobacco; no lawdness." I rejoice to say that out of eighty graduates which will be our number now in a few days—our first class graduated since I came here in 1894—all but five went forth as active Christians. Two of those five were members of churches, and one of these is now preaching the gospel; two others, though not professing Christianity, were very intimate with me. They possessed the Christ spirit in a marked degree. Of our 200 students, one-half the residents are in voluntary Bible-study classes. We see, then, that our unwritten laws are, and will be, more potent and influential than written laws usually are. Thus it will be easily understood why Claremont streets are so free of tobacco. Rarely is the smoker seen, and almost never is a young man, and never a boy, seen with the insignia of slavery and short life—the cigarette—reaching from his lips.

I need not say that Claremont is a good, clean place in which to bring up boys. The great army of smokers is not being recruited in Claremont. Every head of every home circle wishes his boys—how good that I do not need to say girls; (God bless the girls, and help them)—that they stop not with avoidance of the dirty habit, but work with all their great power to keep the boys from his filthy clutch—to let tobacco entirely alone. Even the man enslaved to the habit hopes his boy may be kept from it. I have never heard but one smoker say that he wished his boys to follow in his steps. I am glad indeed that he was so exceptional. But there are few Claremonts. And the great question is: How can we keep the young from this befouling habit that strikes even at the very wealth and life of our splendid American boys? And how from the other dangers that lurk to entrap and tarnish our dear ones?

THE BOY AND THE GARDEN.

It has ever been true—it is true to-day—that Satan is on the eager watch-out for idlers. He knows that they are easily caught. To get the boy or girl thoroughly interested in some good work will more surely rob Satan of his power than aught else. The home circle can undertake no more hopeful or important study than that which will employ all the hands and moments of the boys and girls. Even the city will furnish gardens. We all remember how the governor of Michigan helped the poor by stimulating the growing of potatoes on the vacant lots of Detroit. Can we as fathers occupy ourselves better than in scouring the garden, helping at first to cultivate, to plant, and to glean? Let us insist, however, that it all belongs to the children. Let us praise the neat cultivation, the straight rows, the beautiful, thrifty plants; and let us so advise and direct that there may be no, or few other

ers. Let the children seek the market, prepare the vegetables, etc., in neatest fashion, do their own selling, and, most important of all, let them have *every cent* of the proceeds, to spend as their very own. If rightly guided—and the thoughtful home circle will always keep *guidance* in mind—the money will not go for tobacco, nor nonsense. Very likely it will go for books or papers that will guide to better profits. How rich is the culture that comes from such a scheme, well and successfully carried out! It will surely be the best school the child will ever attend.

I believe in education. I am sure no class can have too much. Were all our people thoroughly and wisely educated, most of the evils of our present society would disappear. I believe the educated farmer may exert a power for good that any man might justly envy. I talked this to my boy long before he entered college. I believe that the teaching that follows boyhood is the teaching that tells.

My boy, before he hardly reached his teens, had such a garden as suggested above. He also had a valuable partner—his younger sister. He also had two very interested spectators to advise, direct and encourage. They were the "tother" part of the home circle. That boy not only secured spending money—he got habits of thrift, of industry, of systematic work; and, best of all, he acquired such a love of the work, that he looked towards agriculture during all his college course, and to-day is an enthusiastic tiller of the soil. He has no use for tobacco, and if he ever uses profane or unclean language, a knowledge of the fact has never reached his father's ear. That little garden was a garden indeed. In it grew richer and better plants than celery or asparagus.

There are gardens and gardens. Setting the table may be the garden for the girl, or she may have a veritable flower-garden that perchance may take her into the sunshine and pathway to robust health. We must secure employment for our dear children. Their good and the safety of our country demand it. He or she that lets the club, business, society, or

even church duties, rob the children of the care and thought that will secure to them habits of thrift, industry, and "patient continuance in well-doing," is making a perilous mistake. He or she who keeps the little hands wisely employed, and the little mind interested in all that the hands find to do, is the good angel of the child. May we not hope that there will be just such good angels in all our home circles? May these good angels be so wise and happy that the work of the child may be at the same time its best play.

MIMICRY.

I don't mean making faces. Bees and wasps are usually beautifully yellow and often brilliantly striped. They love sweets, and so gather thickly about the nectar-bearing flowers. Two-winged flies hover, and for like purpose, about the same flowers. These flies are also yellow and beautifully striped. Often they are so like the bees that only sharpest eyes can tell which is fly and which is bee or wasp. Why this resemblance in color and markings? The bee and wasp have a sting. The bird picks up the handsome wasp only to feel the cruel smart, and spit it out, with a lesson that will save all other wasps from attack by that bird.

The fly has no sting. It could not hurt the bird, and doubtless would be a delicate titbit for bird or youngling. Yet the fly has the wasp color, and the bird is fooled by this, passes the fly, loses the tender steak, and so the fly owes its life to its color-markings.

It is good to get our children interested in just such interesting things that are thick all about us. The cabbage butterfly in its black-dotted robes of white drops its green eggs on the green cabbage-leaves. Their green hides them from bird and insect; and so they are saved to life by mimicry.

The weasel is white in winter and brown in summer, and so profits by its color. Polar animals are white. Who of the children can tell why this white helps the weasel and the polar bear?

AN APIARY OF MR. JOHN W. BAUCKMAN, OF FAIRFAX CO., VA.
(See page 402.)

DESKS FOR GENTLEMEN AND LADIES!

Combined Desk and Book-Case
Size, 66 in. high, 36 in. wide,
19 in. deep.
Price, \$13.75.

THESE DESKS are made of quarter-sawed oak, first-class finish, well put together, and will please every purchaser. They are an ornament to any home, as well as being a useful necessity. Would make a FINE GIFT for father, mother or sister.

The Combination Desk and Book-Case

is just the thing for a farmer or business man of any kind, to keep his private papers in, and for his books, etc. The drawers have locks, and there are a number of pigeon-holes inside each of the desks shown herewith.

The low prices quoted are f.o.b. Chicago. Send for free catalog. Address,

The Royal Star Combination
Game-Board Co.,
773 to 779 Carroll Ave., CHICAGO, ILL.

\$15,000 in Cash to be Given Away

Copyrighted
by the
Press Pub-
lishing
Association.

The Press Publishing Association will give \$15,000 in 1,000 Cash Prizes to those making the nearest estimates in the combined Official Vote of Ohio, Massachusetts and Iowa, cast for Governor on the 5th day of November, 1901.

Estimate the total vote in these three States combined for Governor and send your estimate and subscription to the American Bee Journal, and you will receive a certificate, which will entitle you to participate in the distribution of the \$15,000 to be awarded by the Press Publishing Association, of Detroit, Mich., to those making the nearest estimates of the Official Vote for Governor in the States of Ohio, Massachusetts and Iowa, to be determined by the Election held on the 5th day of November, 1901.

We have made arrangements with the Press Publishing Association, of Detroit, Mich., to enable our subscribers to participate in the distribution of these magnificent prizes, amounting to \$15,000.

Our Offer:

Until Further Notice, every one who sends us a sufficient amount to pay his or her subscription to the American Bee Journal to the end of this year (1901,) provided the subscription is in arrears at least since Jan. 1, 1901; or to any one sending us \$1 for a year in advance of next Jan. 1, 1902, will receive a certificate which will entitle him or her to participate in the distribution of the Prizes. No advance is made in the price of our paper; you get the certificate absolutely free.

YOUR ESTIMATE.—When you send in your subscription you also send your estimate. Be careful to write your name, address and estimate as plainly as possible. As soon as we receive your subscription we will send you a certificate of the Press Publishing Association, of Detroit, Mich., containing your estimate, which will insure you any prize your estimate may entitle you to claim. We will file a duplicate certificate with the Press Publishing Association. Every subscriber may make as many estimates, and will receive as many certificates, as he sends dollars on subscription to the American Bee Journal.

Valuable Information. To aid subscribers in forming their estimate, we furnish the following data:

The combined Official Vote in these three States in

1891 was.....	1,537,493	
1892 was.....	1,684,420	increase 9.56 percent
1893 was.....	1,616,422	decrease 4.04 percent
1894 was.....	1,533,897	decrease 5.10 percent
1895 was.....	1,576,452	increase 2.77 percent
1896 was.....	1,926,718	increase 22.22 percent
1897 was.....	1,572,109	decrease 18.40 percent
1898 was.....	1,532,540	decrease 2.52 percent
1899 was.....	1,963,369	increase 7.89 percent
1900 was.....	1,965,610	increase 18.88 percent

The certificates of the Secretaries of the States named showing the Combined Official Vote will determine who are entitled to the Prizes, and the awards will be made within 30 days after the Official Vote is known.

The American Bee Journal will publish the names of the successful Estimators.

Statement of Mr. W. A. PUNGS,
President of the Central Savings Bank, Detroit, Mich.:

I HEREBY CERTIFY, that the Press Publishing Association has deposited \$15,000 in the Central Savings Bank, Detroit, Mich., for the express purpose of paying the Prizes in their contest on the Combined Official Vote of the States of Ohio, Massachusetts and Iowa, and that this fund can be used for no other purpose.

W. A. Pungs
President Central Savings Bank, Detroit, Mich.

The cash must accompany your order. The American Bee Journal costs you only \$1.00 a year. You get the Certificate absolutely free. Address your orders to

GEORGE W. YORK & CO., 144 & 146 Erie Street, Chicago, Ill.

PRIZES to be Awarded as Follows:

To the nearest correct estimate.....	\$5,000
To the 2d.....	2,500
To the 3d.....	1,000
To the 4th.....	500
To the 5th.....	300
To the 6th.....	200
To the 7th.....	100
To the 8th.....	75
To the 9th.....	50
To the 10th.....	25
To the next 10 nearest.....	\$15 each = 150
To the next 35 nearest.....	10 each = 350
To the next 145 nearest.....	5 each = 710
To the next 160 nearest.....	4 each = 640
To the next 180 nearest.....	3 each = 540
To the next 200 nearest.....	2 each = 400
To the next 240 nearest.....	1 each = 240
Total, 997 prizes, amounting to.....	\$12,800

In addition to the above Prizes, the following Special Prizes will be paid.

To the person making the nearest correct estimate before July 10.....	\$1,000
To the person making the nearest correct estimate between July 10 and Aug. 10.....	700
To the person making the nearest correct estimate between Aug. 10 and Sept. 10.....	500
Total, 1,000 prizes, amounting to.....	\$15,000

In case of a tie, or that two or more estimators are equally correct, prizes will be divided equally between them.

Prospects Poor—Queenless Colony.

There is no prospect of a honey-crop here, as it rains nearly every day, and all bees that have swarmed go straight for the woods. We had an open winter, and bees wintered without loss. Four of my colonies lost their queens, and have been robbed out. I think it better if robbers get started on a queenless colony in the spring, to let them go, as they are never worth trying to save, for the bees are all old, and it spoils a good colony to open the hive before fruit-coming here.

C. G. ASCHA.

Berkshire Co., Mass., June 8.

45 Pounds from One Colony.

My bees are doing well, and I have had five swarms so far this spring. I have taken about 45 pounds of honey from one colony, and there is that much more that is not quite ready to be taken off.

C. C. YOST.

Berks Co., Pa., June 10.

Has Had 3 Swarms Up to Date.

My bees are in good condition. I have had three swarms up to date, and now have 20 colonies.

Most of my neighbors lost from 50 to 75 percent of their bees in wintering. The honey-crop last year was a total failure here.

J. H. RIPP.

Washington Co., Kans., June 8.

Bees Wintered in Fine Condition.

We have 84 colonies of bees which came through the winter in fine condition, only four being lost; but the spring being wet and cold has thus far been very unfavorable for them. We have had no swarms as yet.

CLAWFORD BRIS.

Oscoda Co., Mich., June 1.

Prospects of a Good Honey Crop.

The past year was very disastrous to the bee-business in this locality, as there was no honey gathered last season, and fully half of the bees died of starvation. But the outlook is good for a honey-crop this season, as white clover is doing well.

I fed my bees last fall. I lost one colony in eight through spring dwindling, and now have 10 colonies, most of which are in fair condition.

J. SEIBOLD.

Champaign Co., Ill., June 3.

Imported Queens—Transferring.

The weather has been so dry that the prospect for white clover honey is slim. Bees have built up quite well, and are ready for work. There was considerable loss among some of the bee-keepers here, one man losing 24 colonies out of 75, while others lost 10 or 12 out of 40 or 50. The loss was caused mostly by the queens dying.

My imported queens wintered well. I have received some more queens from Italy in the finest condition of which I have yet had. It pays me to get the best of queens. I have the imported stock that gave me all the surplus honey I got last season, and if I get any this year it will be from them, if strong colonies count for anything.

Some bee-keepers stand up for the little black bees, which may be all right for their locality, but not for ours, or at least I have so found it. I have three colonies of blacks on trial that I transferred about two weeks ago.

I have read of a good many different ways of transferring, so I will give my plan: I first fit up a light board larger than the brood-frames, by laying on it four or five strings of

common wrapping-twine long enough to tie around the frame. Then lay a frame on the strings and take the ends of the strings that are under the bottom-bar and lift them on top. Against the bottom-bar of the frame on the strings I lay a thin strip of wood the same width as the bottom-bar, and just long enough to fit inside of the end-bars of the frame, and I am then ready to place the combs in the frame. I have them as near the full size of the frames as the combs will permit, keeping the combs against the top-bar, and then cutting them even on the lower side, so that the strip that fits inside the brood-frame will touch the lower edge of all the pieces of the comb, always fitting as nearly square as possible. In tying the combs in, I press the strip of wood firmly against the bottom of the comb, so as to tighten the comb against the top-bar of the frame, and hold it firmly till my helper ties the strings, trimming off the strings to within $\frac{3}{4}$ of an inch of the knot, always having the knot come on the edge of the top-bar.

I then take another board larger than the brood-frame, and press hard enough with it to level the "crinks" out of the comb. I next take the first board, comb, frame and all, to the hive I wish to put the bees into, put the frame into the hive, and proceed thus until all the combs are used, and the work is done for a week. After that length of time I take the stick off and what strings the bees haven't removed, and as a rule I get as nice combs as if the bees had done the work in the first place, full sheets of foundation excepted. It is always easiest to transfer during fruit-loom.

ARTHUR A. HOSIER,
McDonough Co., Ill., June 5.

Cold Spring Hard on Bees.

I have had to feed my bees a good deal this spring, because it has been so cold until now when they are beginning to store a little honey.

D. J. BLOCHER,
Stephenson Co., Ill., June 6.

First Honey Taken Off.

I took off my first section of honey to-day. It is light amber, and has a very fine flavor, but I have had nothing in my past experience that will aid me in determining what source it was gathered from. Can you or your Pennsylvania readers give me any assistance?

I planted two acres of buckwheat, May 24, 1900, and kept record of the work done on it by the bees. Do you want the notes? It was successful owing to fortunate showers, but would not always prove so.

Bees wintered very poorly in this locality. I have 36 colonies left out of 52, and all but five of these are strong enough to store sweet clover as soon as it blooms.

L. C. SALISBURY,
Bradford Co., Pa., May 30.

[Perhaps some of our Pennsylvania subscribers can answer as to the source of that first honey.]

Yes, we are always glad to receive notes of an interesting or helpful kind, bearing on the subject to which the Bee Journal is devoted. —EDITOR.]

80 Percent of the Bees Dead.

This is a very poor year for honey in this locality, and 80 percent of the bees are dead. It is so dry that most of the blacks have starved. I still have 16 colonies.

GEO. W. SHRYVER,
Carroll Co., Mo., June 6.

Comments on the Score-Card.

As a member of the committee on score-card, I wish to say to Mr. Hasty that the reason why I ignore drones is because the County and State fairs are held in September, and the drones are mostly killed off in August. I believe it is a rare thing to see drones in nuclei in September, unless they are queenless.

To that item of "Color and Markings," I would prefix the word "Uniformity," so that

it would read "Uniformity of Color and Markings," especially where the golden Italians and the leather-colored compete in the same class.

I like to see the comments and criticisms on the score-card, and hope it will be perfected at the next meeting of the Association.

Juneau Co., Wis., June 10. F. WILSON.

Bees Numb With the Cold—Clovers.

Early yesterday morning (June 9) I noticed bees around their drinking-places numb with the cold. I have many times warmed up the water to prevent them from getting chilled.

Last fall white clover was very abundant—almost like blue-grass soil. But it was not protected by the snow during the winter, and much of it was destroyed. It is only to be found in hollow places, and where it was protected.

Basswood trees have no buds, as far as I have been able to ascertain. Sweet clover is very rank and abundant; the yellow variety is gaining a foothold yearly, and its friends are increasing. We have had no swarms as yet, and there are no prospects of any.

MRS. L. HARRISON,
Peoria Co., Ill., June 9.

Frost and Ice the Last of May.

We had a frost here last night, and ice formed. Bees are killing off drones this morning.

C. J. ANDERSON,
Cook Co., Ill., June 1.

Influence of Queens.

D. B. Norton says in the American Bee-Keeper:

It is a notion with me that a young Italian queen from good stock is a panacea for all bee-diseases. Many a colony dwindles in spring, or is robbed during a dearth of honey in summer because its queen lacked spirit, either from age or some other cause. If you would see the influence of a queen on her bees, take the mildest colony that you have, and also the most irritable, and exchange their queens and note the effect 36 hours after the queens are liberated.

Wintering in an Inside Cellar.

Ira Barber claims that for the best success in wintering not the slightest quantity of air should be allowed to enter directly from the outside, the slightest breath of outer air making the bees anxious to get out. An experience at Medina makes Editor Root seem inclined to become a disciple of Mr. Barber. Thirty-eight colonies were wintered in an inside-cellar in the basement of the machine shop. This basement (perhaps it ought to be called a cellar) is 26x36 feet, with a floor above 7 inches thick, and inside of this was an apartment 8 feet square with no provision for entrance of air only as it entered through several thicknesses of heavy matting and carpeting which formed one of the inside walls. The temperature in the bee-chamber stood at 48 degrees, and there was plenty of fresh air in the surrounding larger room at 40 degrees or more, outer doors or windows being opened whenever necessary to keep down the temperature to 40 or 45 degrees. Notwithstanding the bees were left entirely alone, subject to the tramping of feet and the rumbling of machinery above, the first examination (Feb. 21) showed the bees per-

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00.

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

fectly quiet and healthy—not half a pint of dead bees were on the floor. In gleanings in Bee-Culture we are told how the bees came out, as follows:

On the 1st, 2d, and 3d of May we took all the bees out of the cellar under the machine-shop. They were in fine condition, and apparently just as strong as when they were put in last fall, about the first of December, but had little or no brood. They had been confined just about five months. During all this time they were very quiet, and the number of dead bees on the cellar bottom was the smallest I ever saw. Well, now for the results:

Our Mr. Wardell says that those colonies are away ahead of the outdoor-wintered ones of the same strength last fall. The larger force of bees has enabled them to take care of large quantities of brood, now that they are outdoors; and the probabilities are that, when the honey-flow comes on, they will be worth nearly two of the colonies wintered outdoors. We estimate that our outdoor bees lost very heavily during the grey wintered of April 20—a storm that was a record-breaker, and which will go down in history as one of the heaviest ever known. While the weather was not very cold, yet after the snow had fallen the bees flew out on the warm days following, dropped on the snow, and never got back. Thousands and thousands of bees were housed during this big storm, and were not put on the summer stands till about ten days later.

Ira Barber, in our last issue, recommends putting more bees in the cellar and raising the temperature. Our cellared bees were kept in a higher temperature than any bees we ever wintered during a grey wintered the best, irrespective of the noise above in the machine-shop. But I am afraid that, if the temperature had been as high as Mr. Barber recommends, they would not have fared as well as they did. Nevertheless, we shall test his ideas on a small scale next winter.

Co-operative Queen-Rearing.

The editor of the American Bee-Keeper mentions the scheme of the California beekeepers to have one man rear a definite number of queens for the crowd at a cost of 15 to 25 cents each, but does not grow very enthusiastic over it. He says:

We have great faith in the possibilities of co-operation. It is a plan that Mr. Martin lives by in his plan in successful operation, we confess, is not backed by the implicit faith which we should be pleased to entertain.

Principles of Breeding.

Like those who raise sheep and cattle, beekeepers are breeders of live-stock. The first principle in breeding—the one which every breeder accepts as sound and worthy of all acceptance—is that "like produces like." This is a rule as old as the Scripture that affirms its truth by asking, "Do men gather grapes of thorns or figs of thistles?" It is even older, for you all remember Jacob, the thrifty keeper of the flocks and herds of his father-in-law Laban, and how wisely he managed the breeding, with the inevitable result that "the feeble were Laban's, and the stronger Jacob's."

We expect the offspring to be like the parents. We are sure that the little will not produce the great; we are no less sure that the large will not produce the small. We expect the striking characteristics of the parents to be repeated in their children.

The first rule, then, to be kept in mind by the breeder is, that to have the best he must breed from the best. This is the law. He who violates it suffers the penalty which most of us must bear as best we can, and get along with what is worse than the best.

But the law that "like begets like" must not be interpreted too rigidly. Each of the higher animals has two immediate parents and grandparents without number, and they all have their influence under the same law. The father and the mother are never exactly alike, and the differences in the grandparents

are likely to be greater in number, if not in degree. You have seen children with the appearance of the father and the disposition of the mother—the outer characteristics of one parent and the inner qualities of the other. One child may inherit the weakness of the father and the strength of the mother; another may receive the weakness of the mother and the strength of the father. Unfortunately, the imperfections of both; while one in ten thousand may unite in himself all the good gifts which both his parents could transmit. These choice products of fortunate unions are the hope of the human race; among the domestic animals they are the seed and the secret of progress and improvement.

The great breeders of cattle, horses and sheep recognized these facts, and realized that if they would improve their stock they must breed toward an ideal. To be able to predict results, they must be able, in a measure, to control conditions. This control of conditions in breeding means nothing less than to control the mating of the animals. Without such control there can be no systematic progress in breeding. The intelligent breeder must know his animals, their weak points, as well as their characteristics of strength, and he must bring such animals together as will neutralize each other's defects, and accentuate the points of superiority.

I have spoken of heredity and of what is called variation. These are the fundamental principles in breeding. Heredity determines the type. It holds to what has been gained. It declares that the young shall be what the parents are. Variation provides for progress. It does not annul the law of heredity. It supplants it and makes possible the improvements we hope for, and justifies the use of possible development that has brought all organized animal and vegetable life to its present stage. Heredity is conservative, holding to the doctrine that it is better to retain what is good than to run the risk of spoiling it by struggling toward the unknown. Variation is not satisfied. It insists on making experiments. It is built to breed.

The breeder has his evil genius. Heredity, or conformity to type, is at the bottom of his business. Given the breed or type suited to the man and the situation, and heredity will keep it substantially as it finds it. Given a man who is a real breeder, and he will take advantage of heredity and variation, and improve his animals by selection, by in-and-out breeding, by cross-breeding, and by feeding and care. All the while he must guard against his evil genius, which the wise man call atavism or reversion. Every observant breeder has seen its effects. It is also called "breeding back," "crying back," "throwing back," and other self-explaining names.

Some of you, no doubt, have supposed that I would speak of breeding bees as breeding quince. How could I, knowing nothing on the subject? To open the subject for discussion, let me ask a few questions, first reminding you that I have already called attention to the necessity of controlling conditions in breeding.

There are many who advertise tested queens and pure queens of the several well-known strains, and I believe that there are some who advertise pedigreed queens. Do you know any breeder who controls the mating of his queens? Do you know any one who can say with confidence that his queens have been fertilized by strong, healthy drones from colonies bred to our successful honey-producers? Or, is it true that the breeding of bees is practically natural? Is it true, as I in my ignorance have been led to suspect, that the breeders of queens for the market are not true breeders at all—that they are not sure of the ancestry of the queens they sell, and know nothing of the mating? Is it possible to control the breeding of bees and provide a pedigree that will be a trustworthy record along both male and female lines?—Read by D. W. WORKING, at the Colorado State Convention.

QUEENS!

Improved Golden and Leather-colored Italians are what H. G. QUIRIN rears.

We have one of Root's best long-tongued Red-Clover Breeders from their \$300 queen, and a Golden Breeder from Doolittle, who says if there is a **BREEDER** of golden bees in the U. S. worth \$100, this one is worth that sum. The above breeders have been added to our already improved strain of queens for the coming season. J. L. Gandy, of Humboldt, Neb., wrote us on Aug. 5th, 1900, saying that the colony having one of our queens had already stored over 400 pounds of honey (mostly comb); he states that he is certain that our bees work on Red Clover, as they were the only kind in his locality and apiary.

A. I. Root's folks say that our queens are extra fine, while the editor of the American Bee Journal tells us that he has good reports from our queens from time to time. We have files upon files of unsolicited testimonials.

After considering the above evidence, need you wonder why our orders have increased each year? Give us a trial order and be pleased. We have years of experience in mailing and rearing queens. Safe delivery will be guaranteed, and instructions for introducing sent with each lot of queens.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 19.—New comb honey has not yet reached this market. It would sell at 15¢ per lb if choice white, and the ambers at 12¢ to 13¢. The market is entirely bare with exception of a few cases of a lot that we had held for us, expecting it would be needed. Advertisers are that shipments will be started by July 1. Very little trading is being done in extracted, as large dealers will not contract this season unless at low figures; some sales of amber have been made at 4¢ to 5¢ for early autumn delivery; white is held at 5¢. Beeswax sells at 30¢.

R. A. BURNETT & Co.

DETROIT, June 8.—Strawberries are taking the attention, and very few sales of honey are made, but prices seem to keep up on good lots. Beeswax in fair demand at 27¢ to 28¢.

M. H. HUNT & SON.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from 1/2 to 1 cent per pound.

C. H. W. WEBER.

BOSTON, June 14.—There is practically no comb honey in our market, and owing to warm weather very little call for it. Are expecting some new comb early next month. Market for extracted dull, at 1/2 to 1 cent per pound.

BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00. PEYCKE BROS.

NEW YORK, June 1.—Extracted honey is exceedingly dull and very little moving. We quote for the present: White, 6¢ to 7¢; light amber, 5¢ to 6¢; amber, 5¢ to 5 1/2¢. Some demand for comb honey at unchanged prices. New crop is not beginning to arrive from the South, and sells at from 12¢ to 15¢, according to quality and style. Beeswax, 2¢. HILDRETH & SEGELKEN.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts or stocks and little demand. It is between seasons now. Prospect of good crop in this vicinity from what has been left, the greater portion having been killed by foul brood exterminators. H. R. WRIGHT.

BUFFALO, June 14.—No demand at all. Few old lots here almost unsalable. When new is ready it will sell moderately well at fair opening prices. BATTERSON & Co.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being granulated. Sales are light at 15 cents for best grade No. 1 Colorado. Amber, 13¢. Beeswax firm at 25¢ to 30¢.

W. K. CROMWELL PRODUCE CO., Successors to C. C. Clemons & Co.

SAN FRANCISCO, June 5.—White comb, 11¢ to 12¢ cents; amber, 10¢ to 11¢; dark, 6¢ to 8¢ cents. Extracted, white, 5¢ to 6¢; amber, 4¢ to 5¢; amber, 3¢ to 4¢. Beeswax, 26¢ to 28¢.

Dealers are very bearish in their ideas, but are not securing much honey at the prices they name. In a small way to special trade an advance on quotations is being realized.

California! If you care to know of it! Fruits, Flowers, Climate or Resources, send for a sample copy of California's Favorite Paper—

ITALIAN QUEENS, warranted

Tested, \$1.00; Untested, 75 cents, by return mail.
RIVER FOREST APIARIES,

2141 RIVER FOREST, COOK CO., ILL.
Please mention Bee Journal when writing.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Sweet Clover (white).....	70c	\$1.20	\$2.75	\$5.00
Sweet Clover (yellow).....	\$1.50	2.50	6.25	12.00
Alsike Clover.....	90c	1.70	3.75	7.00
White Clover.....	90c	1.70	4.00	7.50
Alfalfa Clover.....	80c	1.40	3.25	6.00
Japanese Buckwheat.....	30c	.50	1.00	1.60

Prices subject to market changes.

Single pound 5 cents more than the 5-pound rate, and 10 cents extra for postage and sack. Add 25 cents to your order, for cartage, if wanted by freight, or 10 cents per pound if wanted by mail.

GEORGE W. YORK & CO.

I ARISE

To say to the readers of
the BEE JOURNAL that
DOOLITTLE...

has concluded to sell
QUEENS in their season
during 1901, at the
following prices:

- 1 Untested Queen.....\$1.00
- 3 Untested Queens.....1.25
- 1 Tested Queen.....1.25
- 3 Tested Queens.....3.00
- 1 Selected tested queen.....1.50
- 3 " " Queens.....4.00
- 1 Selected Tested Queen,
1st year's rearing.....2.50
- Extra selected breeding,
the very best.....5.00

Circular free, giving particulars regarding each class of Queens, conditions, etc. Address,

G. M. DOOLITTLE,

Barodino, Onondaga Co., N. Y.

A Bee-Keeper's Paradise.

En route to El Paso.—I have just come from a county about 40 miles square that has more bee-keepers to the square mile than any other locality of its size I ever visited. The inhabitants talk bees at the hotels, on the streets, and everywhere, just as farmers talk crops and business in the North. This county produces more honey than any equal area, I believe, in the United States. Some say that its yearly output is a *whole trainload of honey*; but many aver that this is too low, and that two whole trainloads would come nearer the truth. (Of course this great amount doesn't go all in one lot, but in large and small shipments.)

The average per colony is high, and there is a honey crop every season. It is estimated that in this one county, outside of the towns, nearly one-half the population are bee-keepers.

The great bulk of the honey is of the very finest, and some of it is literally water-white. There are thousands and thousands of acres of honey-plants on cheap land; and bees—there are not enough to gather it all.

The bees commence swarming early in the spring; and, when the main honey-flows commence, actually stop swarming, destroy cells, kill off the drones, and commence business. Did you ever hear the like of it before? You say, "No, and no one else." Well, I think I can prove every statement; but for the present I am not at liberty to give the place or other details; but very shortly I'll tell the whole story, with some fine pictures.

This is only one of the good things in store for readers of *Gleanings in Bee-Culture*. Send 15 cents for three months' trial or 25 cents for six months' trial, or \$1.00 for one year and one untested Italian Queen. Send \$2.00 and we will send *Gleanings* one year and one of our Red Clover Queens. Speak quick if you want one.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

☞ If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Key-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto key-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

F. MEHRING, of Germany, the inventor of comb foundation, is also the first one who ever transferred larvae. He described the method and his experience minutely in the Dorf-Zeitung for 1896.—Gleanings in Bee-Culture.

DR. C. C. MILLER, of McHenry Co., Ill., wrote us as follows, June 25:

Yesterday the 100 degree mark was reached, which is just the thing for bee-weather, only we need rain. We started in the season with a shortage, and have never caught up. Red clover leaves curl up with the drouth.

MR. R. V. GOSS, of Jasper Co., Ala., has sent us a picture of his home bee-yard, called "Wildwood Apiary," which will be found on page 426 of this number. Mr. Goss keeps bees for pleasure, preferring them to horses, dogs, etc. The people seen in the engraving are Mr. Goss and his two little "queens"—Mabel and Lois.

W. WANKLER, of Germany, makes the claim in L. Bienenzeitung, 1883, page 112, to have invented and used an implement of his own for measuring bees' tongues. In 1882, He says he exhibited the same at a bee-keepers' meeting and exhibition in Frankfurt, in 1883, where he sold the instrument to Frank Benton.—Gleanings in Bee-Culture.

EDITOR E. R. ROOT is at present doing his work on the fly, and at long range. He is a progressive editor, making a progress of a good many miles some days through the "South country." He complains that a 40-mile rate of speed on a railroad with its accompanying lurches is not conducive to straight writing, but the lines in Gleanings in Bee-Culture appear straight enough.

MR. TOFIELD LEHMAN, of Fayette Co., Iowa, besides being a bee-keeper, is also an amateur photographer. On the first page of this issue, as well as on page 421, will be found samples of his own work.

He began to keep bees in 1892, and has been quite successful during all that time. His bees have been working wonderfully well lately, white clover being plentiful. He looks for a good crop of honey this season.

MR. J. M. RANKIN, the new foul-brood inspector of Michigan, is an energetic sort of chap—one who is bound to succeed in his work. The Bee-Keepers' Review has this to say concerning him: ☐ ☐ ☐

☐ He has nearly completed a course at the Michigan Agricultural College, working his way through, turning a penny in any way that was honorable, even if not always so pleasant.

☐ He was one of the first, if not the first, to call attention to the difference in length of the tongues of different strains of bees, and to urge the breeding of bees with this end in view.

He is very enthusiastic in his work of fighting foul brood; so enthusiastic that, when called away last year to help in its extermination in distant aparies, he would go out moonlight nights and shake off the bees, so as to avoid trouble from robbers. A man that will do that is going to "get there." It is in this enthusiasm that I build my hopes.

(Exact size of the Pen.)

FREE as a.... Premium

A Foster Stylographic PEN....

This pen, consists of a **hard rubber** holder, tapering to a **round point**, and writes as smoothly as a lead-pencil. The **point and needle** of the pen are made of **platinum**, alloyed with **iridium**—substances of great durability which are not affected by the action of any kind of ink.

They hold sufficient ink to write 10,000 words, and **do not leak or blot**.

As they make a line of **uniform width** at all times they are **unequaled for ruling purposes**.

Pens are furnished in neat paper boxes. Each pen is accompanied with full directions, filler and cleaner.

BEAUFOLDING PEN ON THE MARKET.

19,000 Postmasters use this kind of a pen. The Editor of the American Bee Journal uses the "Foster." You should have one also.

How to Get a "Foster" FREE.

Send **TWO NEW SUBSCRIBERS** to the American Bee Journal for one year, with \$2.00; or send \$1.00 for the Pen and your own subscription to the American Bee Journal for one year; or, for \$1.00 we will mail the pen alone. Address,

The Bee-Keeper's Guide;

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without **THE BEE-KEEPER'S GUIDE**.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give AWAY to our present subscribers, for the work of getting NEW subscribers to the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to **PRESENT** subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us **TWO NEW SUBSCRIBERS** to the Bee Journal (with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only **TWO NEW SUBSCRIBERS** to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

No. 27.

Placing Combs on a Wagon. Considerable discussion has occurred, especially in gleanings in Bee-Culture, as to the proper way to place combs to prevent breaking in handling. All agree that on a ear the frame should be placed parallel with the rails, the ends of the frames pointing to the engine. As to hauling on a wagon, however, there was not entire agreement. But a great deal of testimony is to the effect that either on smooth or rough roads the greatest jolting is sidewise, and that the frames should be crosswise, with the ends pointing toward the wheels and not toward the horses.

Contributed Articles.

"Jouncing" Bees Out of Extracting-Supers.

BY C. DAVENPORT.

THE editor of the Bee-Keeper's Review, one of the most prominent men in our ranks, has said that freeing combs from bees is one of the most laborious parts of the work in producing extracted honey. Probably all will agree with him in this, for it is certainly a great deal of work to brush the bees from each comb separately, and for a number of reasons escape-boards are far from being as satisfactory to clear full-depth extracting-stories of bees as they are comb-honey supers. Why this is so I will not take space to explain, for I wish to describe the method I practiced last season, to clear full-depth extracting stories, also comb-honey supers, and what I shall say about this may, in my opinion, be of more practical value to many who are engaged in our pursuit in a large way than the subscription price to this journal would amount to in 25 years.

I feel perfectly free to say this, because the method was not original with me, and I claim no credit whatever for practicing and describing it. Rambler, of California, is the man to whom all honor about this is due, and this matter illustrates not only the value of taking our bee-papers, but also of reading all there is in them. For years I have read those rambles of the Rambler, in many of which there was little said about bees, or anything connected with them, and in some of them he had more to say about girls than about bees—not that I have any objection whatever to reading about girls, (far from it,) but if it was otherwise I should be many times repaid for reading all he wrote.

If some one was to offer me \$50 not to practice this method for 10 years, I would not think of accepting.

This thing, or method, Rambler called a "jouncer," and having, I trust, given full credit to its inventor, I will describe my method of using his invention.

Mine is simply a box about 20 inches long, 12 inches wide, and 10 inches high, ends made of lumber 1 inch thick, and the sides of boards 1/2-inch thick. That is all there is to it—simply a box without top or bottom. Rambler's was better, and made somewhat differently, but mine works well enough.

The method of using it is to set it down in front of a hive which has a super or extracting story we wish to clear of bees. After taking off the cover and giving the bees a few good, strong puffs of smoke, the upper story is taken off and set down on this jouncer, so it rests across the side pieces, which should not be over 1/2-inch thick. Now by the cleats or hand-holes at each end, the super is raised up an inch or so, and then suddenly dropped on the thin side-pieces of the jouncer. This is repeated a few times, and the results are surprising. With full-depth extracting-stories a half-bushel or so of bees will be on the ground around the jouncer.

As I have said, this is set right in front of their hive and the bees soon crawl in. Until one tries it he would not believe the ease and rapidity with which bees can be jarred or jounced out in this way, after one acquires the knack of doing it just right. It takes longer and requires more jouncing to clear a super of comb-honey than it does an extracting super, for many of the bees, when they fall from the combs, strike the bottom of the sections, which prevents them from falling out. With extracting-combs there is nothing to prevent their falling out on the ground. But most of the bees in the sections can be jarred out in this way more easily, in my opinion, than the supers can be cleared by escape-boards. Besides, what I regard as a great advantage of this plan over escapes is, that the work is done at once, in one operation. It is the method I employed exclusively last season with all surplus that came off the hives. And, seriously, I consider it one of the most valuable things I have learned in regard to our pursuit in many years.

Of course not all the bees can be jarred off in this way, but near enough so I pay no attention to what are left. The honey-house is right in the yard, the windows of which are arranged to allow bees inside to escape, but they prevent those outside from entering; so after jarring out

in this way what bees I readily can from a super, it is carried in, and what bees are left soon find their way outside.

When a large number of supers are carried in at one time, they are piled cross-wise of each other. This is important, to have the bees leave the supers and house readily. When the supers are tied up tight in the regular way, many of the bees will range up and down the whole tier a long time before they seem to feel convinced that they can not find their friends and mother somewhere in the piles.

I have seen it advised where the honey-house was in or near the yard, to carry in the supers—bees and all—or at least as many of them as would not readily leave by the use of smoke. But this plan, as no doubt those who have practiced it in a large way will be willing to testify, is a very poor method to practice. It will work in a small way, but when a good many bees are in each super, and a large number of supers are carried in at one time, there is such a mass of bees inside that they can not very soon leave by an ordinary escape; and when there are such great numbers they do not, for some reason, seem to wish to leave. I have had large bunches of them hang around to the rafters overhead for days, when there was nothing to prevent their escaping, and after being thrown outdoors many of them would hover around the door and windows, and again enter if they got a chance. When such a great horde are carried in, the noise and confusion that occurs, or something else, seems to effect or derange many in some way so that they take little interest in the world afterwards, or even seem to know where they are or belong. Some may think that these young bees are not old enough to know the location of their hive; they are bees of all ages—young, middle-aged, and old—and during the working season it is not difficult to tell pretty closely how old a bee is; but the worst part of this method with section-honey is that considerable of it may be consumed and damaged by these bees that stay in the house and supers so long, for they do not hesitate to eat what honey they need, or rather apparently, all they can possibly consume.

But what bees I can not jounce out leave the house readily, and with extracting-frames what few bees are left bother but little, even if extracting is commenced as soon as the supers are carried in.

It would be natural for one to think that it would be hard, heavy work to jounce in this way full-depth stories that are well-filled. It is not, though, for a man of average strength with S-frame hives; and it is a great pleasure to see the bees roll out.

Still, many who read this, and try the plan, may regret that I ever wrote anything in regard to it, for by this method it is a very easy matter to break extracting-combs, especially new, unwired ones. I broke a number before I acquired the knack of doing it right, and found out just how hard a jounce new combs could stand. But this was little loss, for I fastened them in the frames again with twine, and the bees attended to the rest even to cutting off and carrying out the strings after they had the combs fastened.

Sections, the combs of which are but slightly attached at the top only, can also be readily broken loose by jouncing; but I use bottom starters in sections, which insures the combs being fastened to the wood more than strong enough to endure what jarring is necessary to clear them of bees. This jouncing does not need to be heavy and hard—a very quick, light jounce will accomplish more. The super should be raised but slightly each time. It is the quick, rapid jars that cause the bees to loosen their grip and roll out.

Southern Minnesota.

Prove Theories Before Accepting—A Correction on the Dickel Theory.

BY F. GREINER.

ON page 359, Prof. A. J. Cook gives us a very interesting article on the Dzierzon and Dickel theories. After reading it carefully I am satisfied that no one else would write it as ably and use all the scientific terms correctly. The article contains two minor points which, according to my conception, are not fully true, to which I draw the attention of the Professor as well as the thinking reader.

Prof. Cook says in regard to the queen laying fertilized and unfertilized eggs: "The queen adds or withholds the sperm-cell at will." It is pretty clearly proven by the late experiments of Weisman, that the queen does lay fer-

tilized and unfertilized eggs, but that she should do so at will is nowhere proven, to my knowledge. It is very doubtful in my mind that it ever will be. Without any fear of being proven incorrect, I might claim that the queen always acts compulsorily, that she can not do any differently than add sperm to the worker-egg, and withhold it from the drone-egg. In fact, it seems more reasonable to suppose that these delicate and peculiar organs of the queen act involuntarily, the same as they do in other living beings. We have heard it and read it so much, that a queen can fertilize eggs at will—we have been brought up with this idea—that we scarcely give it any thought. We take it for granted that it is so. Where is there any proof? All we really do know is that she lays both fertilized and unfertilized eggs, and places them in different sized cells, each kind in a special cell; but we jump to the conclusion that she does it knowingly.

It is misleading to speak positively of a thing we do not know. As long as we consider it a theory, an assumption,

PART OF HOME APIARY OF TOFIELD LEHMAN.—See page 418.

tion, some inquisitive mind may be induced to ferret the matter to the end.

As to the worker-bees determining the sex of the egg, the Professor quotes and criticises Dickel as follows:

"Dickel thinks that they [the bees] add saliva [to the egg after it has been deposited in the cell.] In case he is correct in his observation, his conclusion that this has something to do with determining sex does not follow."

On this point I beg to say that Dickel does *not* claim that *saliva* added to the egg determines its sex; he claims this for *another* secretion, the product of a special set of glands (of systems II and III, according to Dickel), the secretion of one determining the male, of the other the female, the secretions of both systems combined determining the sex or nature of the worker. On this basis Dickel attempts to explain how it comes about that abnormally-built workers develop. Perhaps not many of us have observed these funny-looking workers with a drone-like head. Under "Questions and Answers," page 360, such are spoken of. It would be interesting to know how the queen that produced these bees would behave in some other colony.

It is not my object to criticise Prof. Cook—I simply wish to draw attention to these facts as I understand them. Ontario Co., N. Y.

An Italian "Atlas of Bee-Culture."

BY C. P. DAPIANT.

M. R. A. DE RAUSCHENFELS publishes in Milan, Italy, a new edition of the magnificent chromos of the anatomy of the honey-bee, drawn by the Signor Clerici, after the microscopic studies of Count Gaetano Cerchi, which were originally published some 25 years ago, under the auspices of the Central Association of encouragement to bee-culture in Italy. A copy of this work is before me.

The present issue, instead of being in detached plates, as formerly, is in the shape of an Atlas (Atlante Di Apicoltura) and gives, not only the 30 chromos, in book form, but also a descriptive text opposite each plate. In addition, an extensive and thorough treatise on bee-culture, of the same size, and containing 380 pages and numerous engravings, accompanies the atlas. The title of the latter work is, "L'Apicoltura e la sua coltivazione"—The Honey-bee and Its Cultivation."

Although many have been the microscopic studies, and many have been the publications on the honey-bee, nothing more extensive and more accurate has ever been produced. Girard's cuts, as is well known, are all reduced copies of these chromos. Others have borrowed from them also. The work is now in such a fine shape that it is to be regretted that it has not been published also in a more universal language than the Italian.

The following is a synopsis of the contents of the Atlas:

Plate 1.—A comb with worker-cells, drone-cells, queen-cells, both sealed and unsealed.

Plate 2.—An Italian queen, magnified to 7 inches in length.

Plate 3.—The head of a queen magnified to 2½ inches.

Plate 4.—The genital organs of the queen, the ovaries, ducts and spermatheca.

Plate 5.—Eggs and larva, highly magnified.

Plate 6.—The curved sting of the queen-bee, showing the very diminutive poison-sac, and abortive poison-glands.

Plate 7.—The drone magnified to 6 inches in length (Italian drone).

Plate 8.—The head of the drone, showing the large compound eyes, ocelli, and small mandibles.

Plate 9.—The ocelli, or smaller eyes, of the drone, magnified 45 diameters.

Plate 10.—Sexual organs of the drone, the penis, sperm-glands, etc.

Plate 11.—The penis of the drone magnified 15 diameters. Spermatozoa of the fertilizing fluid, magnified 150 diameters.

Plate 12.—The worker-bee, Italian.

Plate 13.—The head of the worker-bee, diameter 3 inches, the antenna magnified to 2½ inches in length.

Plate 14.—The composite eye of the worker-bee magnified to 4 inches.

Plate 15.—The tongue of the worker-bee, magnified to a length of 7½ inches.

Plate 16.—The wing of the worker-bee magnified to the length of 7½ inches. This is hardly up to Cheshire's cut of the same thing, as it does not show plainly the plait and hooklets by which the parts of the wing are hinged together in flight. This is most thoroughly shown in Cheshire's work.

Plate 17.—Anterior and posterior legs of the worker-bee. This is not quite so much detailed as Cheshire's.

Plate 18.—Main artery, which, as we understand it, is practically the heart of the bee (*Vaso pulsante*).

Plate 20.—Salivary glands of the worker-bee. These are the glands which are believed to help prepare the royal jelly, and give the peculiar bee-flavor to honey. Much discussion among scientists has taken place concerning this matter.

Plate 21.—The breathing apparatus of the bee—airsacs, trachea, and breathing orifices.

Plate 22.—Digestive apparatus of the worker-bee showing the tongue and its appendages, the honey-sac, stomach, Malpighian tubes, and intestines to the end of the rectum.

Plate 23.—Sexual organs of the worker-bee. Atrophied ovaries of a worker; ovaries of a drone-laying worker.

Plate 24.—The wax-producing organs.

Plate 25.—The sting of the worker-bee.

Plate 26.—Nymph or chrysalis of a worker-bee, during its transformation, or metamorphosis.

Plate 27.—Microscopic view of foul brood, now called "bacillus alvei."

Plate 28.—Magnified cut of bee-moth, miller and worm.

Plate 29.—Braula *cucica* or bee-louse, magnified. Also mandible of fruit-piercing wasps.

Plate 30.—The death-head moth (*Sphinx atropos*), a large moth which is said to enter the hives, in Europe, and feed upon the honey in spite of the bees.

The price of the work, both volumes, is 12 lire. It could probably be furnished to American students for about \$3.00 per copy. It is a fine work of art, well worthy of the country in which it has been produced—the birthplace of fine arts. Hancock Co., Ill.

No. 2. Some Reminiscences of an Old Bee-Keeper.

BY THADDEUS SMITH.

It is not my intention to go into the history of the first invention or use of the movable-comb hive, as I have not the statistics, and it does not come within the scope of these papers. Mr. Langstroth's patent, I think, was issued in 1852, or about that time, and he admits that some kind of movable combs were used in hives in Europe by Munn, Huber, Dzierzon, and perhaps others, some eight or ten years before his invention or improvements on the hive. I have not even Mr. Langstroth's book before me to refer to on these matters, and I do not wish to go beyond my own memory, assisted by reference to some numbers of the old American Bee Journal.

The invention and introduction of movable-frame hives certainly created a new era in bee-keeping in this country, and the introduction of the Italian bee about the same time gave a still greater impetus to the business. But the Italian bee would have made slow progress in this country had it not been for the movable-comb hive—probably it never would have been disseminated here at all to any great extent.

When Mr. Langstroth offered the first practical working movable-frame hive to the country, involving principles that had never been used in any hive in Europe, there were many, I might say hundreds of imitators and those who professed to have made improvements upon the standard Langstroth hive by making all sorts of changes, mostly of little, and many of no, importance; and on many of these changes and so-called improvements patents were taken out when the only thing of real merit about them was the movable-frame principles of Mr. Langstroth's patent. Scores of these hives, patented and non-patented, were offered and highly commended to the bee-keeping public, the most of them taking the name of their introducer. We had the Quinby hive, King hive, Alley hive, the Flanders three-cornered or Diamond hive, Thomas hive, American hive, Adair's "New Idea hive," "The long Ideal Hive," Gallup hive, Heddon hive, and Price's Reversible, Revolvable hive, and—I think I would better end the list here, for time and space forbid the mention of all of them.

Mr. H. R. King was probably the most persistent of these so-called new hive inventors, in trying to invalidate Mr. Langstroth's claims to originality in his hive. He made a trip to Europe and spent thousands of dollars for the purpose of collecting evidence to disprove Mr. Langstroth's claims. He found, as I have stated in the beginning of this article, that frames of some kind had been used by certain ones in Europe some years previous to Mr. Langstroth's invention; but they all proved so different from Mr. Langstroth's hive, and so crude in comparison, that Mr. Langstroth's claims were sustained in the suit brought to test the matter. N. C. Mitchell was another hive patentee who violently assailed Mr. Langstroth's claims, and established a new bee-paper for that purpose. In the early seventies the battle of the bee-hive men waxed warm indeed.

The only hive besides the Langstroth, of the new patents, that I was ever induced to try, was that of J. H. Thomas, of Canada. Mr. Thomas set forth the claims of his hive in numerous letters to the American Bee Journal and other prints, and boldly stated that he had "the best hive in America." About that time I had left "my old Kentucky home, far away," and was located in the Queen's Dominion, on Pelee Island, and although I had brought with me the Langstroth hive as made in Cleveland, Ohio, I concluded to try the Thomas hive, and ordered half a dozen.

This hive was an admirable adaptation of frames to the form of the old box-hive—tall in proportion to length and breadth, was well made, and of neat appearance. For surplus there was the ordinary cap, covering a neat honey-box with glass in each end. There were but eight frames, and they were fixed so as to be stationary, but still by a peculiar arrangement were very easily handled. It had a sloping bottom-board with a lot of minor "fixings" of no especial value. The frames, of course, were large. Soon after this I became the owner of a Peabody honey-extractor, and the Thomas hives did not suit me. I abandoned the use of them, although I had made a number besides those I bought. There is one about now, in first-rate state of preservation for having laid in the lumber-room of my barn for the past 20 years; others went for hen's nests and chicken-boxes.

As so many were getting up new hives—patented and

non-patented—your humble servant thought he could get up one, too—of course, an improvement on anything that he had seen or heard of!

I early became greatly interested in Mr. Gallup and his writings, of whom I may have more to say under another head; and took his hive and descriptions for my model—with changes and improvements, of course! May I be pardoned for giving an extract from an article on "The Hive Question," printed over 30 years ago, descriptive of my hive, as I wish to make some comments on it in connection with other hives. Here is an extract:

"I have made a hive on the plan of Mr. Gallup, that I believe possesses many advantages, and is capable of being used many ways, with the same size frame for all the different styles, than any hive I have seen described. The brood apartment is the plain box of Mr. Gallup—11 inches wide, 11 inches deep, 18 inches long, or as much longer as may be desired. The frames are hung across the narrow way. We can use this hive, 1st, as a simple frame hive with large room on top for surplus-boxes; 2d, by extending the length to any desired number of frames; frames for surplus honey may be put in each end for emptying with the extractor; 3d, it can easily be made a two-story hive with the same size frames in the upper story; 4th, by having movable side-boards it may be made a non-swarmier, on Mr. Quinby's and Mr. Alley's principle, and piles of honey-boxes may be put on the sides and top. I have one with 13 frames, 16 five-pound boxes form the sides, and three 12-pound boxes on top—all enclosed in a suitable case. From all that I have read on the subject of hives, I think that I have hit the golden mean in width and depth. I call this hive, with its non-swarming and box arrangements, the "Quinquaplex-Duplex-Combination-Non-patented-Super-floors-Honey-producing Hive." It is said there is nothing in a name, but if I could only get Mr. Price's "Reversible-Revolvable" attachment, with the privilege of adding the name, there would be considerable improvement in adopting this compilation for the modified arrangement."

Of course the name was intended as a burlesque on the many claims of some other hives. But I was in earnest in thinking that I had the "golden mean" in size, and a good thing in a hive that could be used in so many different ways with the same frame, but I never applied for a patent nor offered a hive or a "territory" for sale, though I had material got out in the flat for 50 hives for my own use.

I had a hive made with open side and side-boxes, as described—the non-swarmier; I put two hives together end-wise, and had the "long-ideal" hive. I put two side by side, with one side of each open, and had the "twin hive," and by putting one on top of the other I had the two-story hive, or three stories, if desired, as I have sometimes used them.

I have recently read where the writer of the article said in effect: "Before you go into side-storing surplus arrangements extensively, first find out if you have the side-storing kind of bees." I was not long in finding out that my bees were not the side-storing kind, and all my hives except the two stories went to the lumber-room. I think some are there yet—have been for 20 years. I am using some of these hives now as two-story—25 frames for extracting; and they make good supers for my chaff Langstroth hives. For better wintering I made some with double walls with air-spaces.

I have found it to my advantage to use the extractor, and these frames work well in it. I bought the Peabody as soon as I heard of it on the market. It looks as if it would never wear out, but I got a better one a number of years ago—the Cowan reversible.

It is undoubtedly true that there have been many improvements made upon the original Langstroth hive in the first form given to us, especially the box that contained the frames. The introduction of the extractor, the more general use of section surplus boxes, and general advancement that has been made in bee-keeping in the last half century, demanded something different—more simple in construction, and better adapted to present wants, but maintaining the same principles of the movable comb that Mr. Langstroth invented; and the great majority of the hives now in use have the same size frame, with the same relative proportions as first recommended by Mr. Langstroth, and those in which but small changes have been made from the Langstroth frame are in almost universal use in this country.

And where are the hives of King, of Thomas, of Flanders, and of the whole list of these so-called improved hives? Echo answers, "Where?" We certainly hear but little from them now through the press. And their makers and inventors? Many no doubt, like Mr. Langstroth, have passed over the border to the Beyond, where they are free, we hope, from toil, envy and strife. And the rest of us old fellows—their cotemporaries—must, in the nature of things, soon follow. Ontario, Canada.

Swarming—Moving Bees—Queens, Etc.

BY J. M. DAVIS.

"LOOK! that's a whoppin' big swarm, whars yer cow-bell? Guess I ken stop 'em."

"Oh! Tom, don't hop so excitedly, and don't punch a hole in the bottom of my wax-extractor. Just let them alone, and you will soon see they will settle without any music. Hand me that little wire cage off the shelf, and come with me, no danger at all. See, here's the queen climbing this blade of grass. Ah! that's accommodating. Just to walk right into the cage, off the grass. See, Tom, they are clustering in the top of that apple-tree?"

"Wal, Kunnel, that's the first swarm of bees I ever saw stopped without a racket. That's the purtiest and longest bee I ever saw, why, she is as yellor as gold. Wat was she skirutin' in the grass fur? Tho't kings went up with the swarm."

"Well, Tom, you stick to your kings, loyally—but you will have to desert your cuillors. Queens rule here. I keep one wing clipped off all my queens to prevent them leaving with the bees. See this one has her wing clipped."

"I declar, the idee of cuttin' off a bee's wing, Sara Jane cuts her chickens' and turkeys' wings off to keep them out of the gardin; but I never'd a tho't of cuttin' a bee's wing. What's yer saw? I'll jist clime that tree and saw off the limb for you, Kunnel."

"Oh! never mind doing that, Tom. Please jist help me move the old hive back here—that's alright. Now, kindly help me place this new hive in place of the old one, there, now place the caged queen at the entrance over at that shady corner. You will now see how I hive bees."

"Yes, and I told you Kunnel, to let me rap on the old basin, or they will lite out."

"No, Tom, you jist wait, see they are coming down to the new hive on the old stand, and are going in nicely—now you may unstop the cage and let the queen go in with them. See how quick she went in; now the job is done, they will all be back in a few minutes, and soon be at work again. I think we have given the imported bees time to have their flight; so let's take a look at her ladyship, the queen."

"Why, yes, they are working as nicely as any colony in the yard, although they haven't been here two hours. I will first remove the screws that hold on this frame covered with wire-cloth, you see they have all gone down. This frame is two inches deep, but when we arrived it was full of bees clustered so as to relieve the brood-chamber of as much heat as possible. In warm weather they need fresh air, therefore when we move them far, an extra space for a part of them to cluster in should be furnished, and the hive covered with wire-cloth, then there is less danger of overheating and melting the combs down."

"What's thet sponge for Kunnel, tha don't cypher do tha?"

"No, Tom, that held their drinking water, see [squeezing] they used nearly all of the water. This enabled them to keep the young brood alive during the journey. A few folds of old linen, or cotton cloth, answers very well soaked with water, and laid on the frames as was this sponge."

"These corrugated sticks were put in to hold the frames apart, one at each end on top and one in the center at the bottom. I will place them in this new hive as I remove the frames and then I won't be bothered with the corrugated stick on the bottom."

"Why, Kunnel, they seem to fit jist as well in this gum as t'other. How did you hapen to git 'em so alike, four hundred miles away?"

"Tom, these hives are made and shipped all over the country; every piece fits any hive, no matter if you buy it in Australia. It would be a great help to us for all bee-keepers to use a standard frame; and I will be glad to see one adopted. See, here is the queen and a fine one she is."

"Thet's tru', Kunnel, she's a whopper, broader between the shoulders and longer than t'other one, but not so purty gold-like, as t'other one, and these bees are longer too, but three strips of gold around them. T'other was nearly all gold lookin'. Say, Kunnel, what on airth is she crawfishin' into thet cell fur, has she got down to rest?"

"Ha! ha! why she is depositing an egg. Tom, see, she is through, and peeping into other cells to find an empty one—there, watch her."

"Now, if that ain't funny, didn't she hump thet long back and crawfish as purty like. Say, Kunnel, I hev heard of hens laying t'wo eggs a day, but I never bleyed they could

do it. Look, thet old buzzy is humpin' her bak agin. Well, that's three in a minute and a half, is she all eggs?"

"Very nearly so, Tom; at least she can deposit from three to four thousand eggs in a day of twenty-four hours. You see, they do not stop at night. These eggs would make a pile about as long as the queen I think."

"Gee, whiz! Wish we could get some Italian chickens and geese and turkeys an' ducks. Can't you 'port 'em Kunnel?"

"We could get them, Tom, but they would be no better than yours, probably not as good. I see my wife at the window waving her handkerchief, and here I've been over two hours without going up to see whether she was dead or alive. I became so engrossed with my bees that I forgot everything, and I just now remember I haven't had my breakfast and dinner. You see she pets me some when I've been away."

"Thanks, Kunnel, I jist tho't of it, Bil Johnsin sed he'd cum to my house at ten o'clock to buy my yearlings and I reckon he thinks I have left these diggens. I will hev to hurry on. I got that ocydide with the bees that I forgot everything 'cept Sara Jane, and I jes wish she war here to see 'em."

"Very glad to see you take such an interest in them, and you seem not to be afraid of them now. I will need some help this summer, and if you can come over and bring Jake to-morrow, we will extract some honey, and see if I can't give you some further instructions. Say, Tom, you need not wear out your cow-bells ringing down your swarms, jist spend that time getting your hive ready, and you will spend it more profitably."

"Kunnel, I will be ded sho to come and bring Jake to-morrow an' help you. Jake is a peart lad, jist twelve yest'day an he's mity fond of bees. I see your wife shakin' thet 'kerchief at you, and you had better go, or she will be after you. Good evening, Kunnel."

"Good evening, Tom, I shall expect you."

"Good mornin', Kunnel, Jake and me hev been here two hours and Sara Jane she tho't we would be late."

"Good morning, Tom, and Master Jake, I am especially glad to see little boy bee-keepers. They make the best ones in the end. Tom, you see the bees are cross early in the morning. The sun has warmed them up now, so we will get to work, everything is ready."

"Well, Kunnel, Jake he's mighty struck and ses he's goin' to be a bee-keeper and get some *hitalan* bees."

"Alright, my boy, I will help you get started. Now bring out the wheel-barrow, and nine dry combs, while I start the smoker. I always have it handy—but use it as little as possible. I find cedar bark, well packed, lasts longer, and gives the best volume of smoke of any fuel. Here is number one, see, I gently pry off the top, and use jist a little smoke, push several frames jist a little nearer together, so as to get room to draw out a frame without crushing the bees. Now I give the frame a quick jerk, which you see clears the comb of most of the bees, and this long turkey feather soon gets off the balance; now as we have out three frames of honey, I will put in one of the empty combs every time I take out a full one. Here is one full of honey, but not capped; we will leave that, as it is too thin when not sealed to make a good grade of honey. It is not 'ripe.' After extracting this honey, we will exchange the empty combs with number two, for her full combs, and so on through the apiary. Tom, draw your honey-knife across the sharp edge of the cross-piece over the uncapping can, to clear off the honey, and when the knife gets gummy put it in a bucket of water, which dissolves the honey, and you will find that it will then shave off the cappings nicely. Here is a new tender comb, and I will have to turn the extractor much slower to prevent breaking the comb."

"Kunnel, sum of these combs are made of black wax, and sum of white wax, whar do they get the different colors?"

"All combs are like this new one when first made, but become black with age. I have old black combs jist thirty years old, but I get jist as nice clear honey from them, as from these new ones—besides they are tough and stand more rough handling than new comb."

"Kunnel, here is a low gum. What we goin' to do here?"

"Let us see how they are getting along. Oh! nicely, they are sticking on little bits of white wax along the top cells, and are crowded with bees. Hand me that queen-excluding zinc off the wheel-barrow, and I will put on these freshly extracted combs, which will put them right to

work in the super. Jake, you run up into the extracting room, and get us nine empty frames for the next hive. Well, this is the last hive, and we have taken about four thousand pounds in ten and a half days. Now, I want to arrange cells for a few hundred queens. We will not need our smoker, as I do not breed from cross bees."

"Wat's them little yaller things you're gittin,' Kunnel?"

"Queen-cells, Tom."

"They are mity purty, Kunnel. Does the queen stick them on the little stick that way?"

"No, Tom, the queens do nothing except deposit eggs. My little daughter, Annie Dane, makes these for me, it is just fun for her, and saves me a great deal of time, as I use hundreds of them."

"Well, I declar, that child is only eight years old, an makes such nice little things? Looks to me like it would take a reglar jueler to do sich work, how on airth does she make them so thin and smooth at the mouth and so round and nice?"

"I will lend you a book, written by Doolittle, that explains this fully, and let me say right here, Tom, I would not go back to the old method of queen-rearing for one thousand dollars cash. That book is worth its weight in fine gold."

"Well, Kunnel, I will put it under my piller every nite and bring it back soon as Sara Jane and me and Jake reads it; an we will be mity proud to read it. Wat's thet quill spoon for, Kunnel?"

"This is to transfer the larvæ from the worker-cells to the queen-cells. I will show you the modus operandi. Here are eighteen cells in this hive nearly ready to cap over. See, twelve are large and rough, four are smaller and rather smoother. I always destroy such cells, so I will take these four, and use their royal jelly to put in these new cells—hand me the stick, Jake."

"Why, Kunnel, here's a worm in this one, is it a moth?"

"No, Tom, it is a young queen, see I can throw them out this way, and dip up a small quantity of the royal jelly with my quill spoon, and place it in the bottom of the new queen-cells, thus; now, I have fixed thirty-two cells. I will get the larvæ from the 'Berberini' imported queen. See, I remove this dummy first, and find the queen."

"There she is, Kunnel, on thet frame."

"Thanks, Tom, your eyes are keen. You see I can not afford to risk dropping so fine a queen in the grass or to injure her, therefore I never take any chances. I will just take this frame and leave her in the hive. See, here is plenty larvæ just the right size, about twelve to twenty-four hours old. I slip my quill spoon under them this way, raise them out and slowly lower them into my queen-cells, until the point of the quill just touches the royal jelly at the bottom, and by drawing it back, the little larvæ sticks to the royal jelly, which is in its nature glutinous. Now all the cells on this stick have larvæ in them. I will place it between these two combs of brood in super of number 50. See the stick fits tightly in this frame half filled with comb, and the brood on both sides will help keep the little queens warm, as the bees cover these combs all the time."

"Why, Kunnel, won't the little queens fall out, with the mouths of the cells down thet way? And how on airth do you take little worker-bees an make queens outen them?"

"No, Tom, they won't fall out, the jelly holds them, and its their nature to grow with their heads down. Never horizontally, like a worker-bee. The peculiar food given them in great abundance, and developing in large perpendicular cells, transforms them into queens."

Now, that I have my one hundred queen-cells stocked with larvæ, I will take out some ripe cells."

"Wat do you mean by ripe cells, Kunnel?"

"A ripe queen-cell is as easily distinguished as a ripe apple. See this stick of queen-cells. The points are all light-colored and pointed, these will be not ripe for several days. Now here is a stick of cells that will hatch to-morrow. See they have blunt flat ends that are brown, and rough. The bees knowing that the young queens will want to come out to-morrow, are helping them by trimming off the points of the cells. I take them off the day before they are dne, and carefully place them in the half-inch holes you see in this block, with the points resting on the little wool cushions so as not to jar, or injure the young queen. I have only twelve ripe cells this time. Tom, here is what we call a queen-nursery, which is merely a very small swarm of bees—enough to cover well, two or three Langstroth combs."

See this patch of brood? I place the cells thus, just above the brood and press it into the comb. See, no danger in pressing a Doolittle cell into a comb that way, but a very light pressure would destroy a natural cell. This nursery has been queenless two days, and will gladly accept the cell. Now here is a nursery containing a queen that I wish to mail to-night. Here she is; see I remove the cork in the end of this cage, and pick her up by both wings poke her head in the hole from which I took the cork, thus. See, she went in nicely, and to keep her there, I place the end of my thumb over the hole until I can put in ten or a dozen workers *not too young*. Now all are in, I replace the cork, tack on the cover, thus. Now I will put on a one-cent stamp and send them to the post-office. I will have to protect the cell, or the bees will destroy it before they miss their queen. This wire-cell protector prevents this, and by the time the young queen emerges from the cell, they will have discovered the loss and will gladly receive her. In two days she will be laying and I will ship her, give them another cell, and continue to do this until the season is over."

"Well, Jake, here is the new hive with foundation, all ready to hive your swarm on. You shall have a nice queen, a descendant of the Berberini stock, as soon as your colony is ready for her, and I predict that a progressive young bee-keeper will make his start with this colony."—Progressive Bee-Keeper.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Swarming—Long-Tongued Bees.

I take some encouragement from the letters of C. H. Harlan and F. M. Creighton, page 390, in knowing that sharp eyes are upon me with kindly hearts behind them. Mr. Harlan's statement is exceedingly interesting, and I am wondering whether he has exceptional bees or an exceptional locality. I wish he would give a little fuller light upon it. When he hives the first swarm in a new hive, if I understand him, he cuts out all queen-cells but one in the old hive, and then a little after this a swarm issues with the young queen from the cell that was left. Now, how long after the cutting out of the cells does this swarming occur? Then does he mean that from this same old colony a third swarm will issue six or eight weeks after the issuing of the second?

Mr. Creighton thinks that long tongues would be of no advantage in his locality. He is no doubt in a very large company who think only of red clover as the one honey-plant to give value to long tongues. A correspondent in the Southland Queen speaks of a honey-plant with tubes so deep that the bees only get part of the nectar, and he thinks long tongues are needed to get it. Mr. Doolittle says, page 293, "long-tongued bees would be an advantage to those residing where red clover and other long-tubed flowers abound." (Italics mine.) Is it not possible that these long-tubed flowers are generally distributed everywhere? Does Mr. Creighton know that within the range of his bees there are no flower-tubes so deep that his bees can not reach all the nectar in them? If he does not know this, then he does not know that long-tongued bees "would store no more honey" for him. If he does know it, will he kindly tell us how he knows it? But I'll throw up my hat with him, and hurrah for the bees that don't swarm, in preference to the ones that get the red clover honey.

C. C. MILLER.

Swarm Left After Being Hived.

At noon to-day I hived a large swarm of bees, then set the hive beside the old one that the bees came from, intending, when I came home from the shop at 6 o'clock, to change places with them, putting the new one where the old one was; but at 6 o'clock there were no bees in the new hive. Do you think they went back into the old hive, or left for

the woods? The entrances both faced the same way, and were close together. The new hive contained full frames of comb with a little honey in some of them.

CONNECTICUT.

ANSWER.—I don't know, but I'm afraid they went to the woods. At any rate, without knowing anything about the cases except that 100 large swarms after being hived had deserted their hives, I should feel pretty safe in saying that not more than one or two of them had gone back to the hive from which they came. You ought to be able to tell something about it by the appearance of the old colony. If the swarm did not return to it, the scarcity of bees ought to be easily noticed. The position of the hive had nothing to do in the case, except that it would help to make the bees desert if the hive stood in the hot sun. The chief factor in inducing a swarm to desert its hive is heat. Be sure that the hive is very open at the bottom, and for a day or so it is well to have the cover a little open, and if the hive does not stand in a shady place use some means to shade it, if nothing better to cover it with an armful of long grass or hay, anchored down with two or three sticks of stove-wood. Some make a practice of giving to a swarm a frame of brood.

Self-Hiving Arrangements for Swarms.

Can bees, when swarming, be transferred to a new hive by closing the opening in the old and new hive so as to be queen-tight, except a wire gauze connecting the two hives through which the queen could pass into the new hive, and the worker-bees to pass out and in as usual? If this plan would not work at all, please say what the objections would be.

WASHINGTON.

ANSWER.—Several different arrangements have been gotten up on the principle you mention. I don't know enough to tell you exactly as to the objections, but I think none of them have given enough satisfaction to be continued.

Are Bees Taxed in Wisconsin?

Are bees assessable for taxation in Wisconsin?

WISCONSIN.

ANSWER.—I don't know. A lawyer, or an assessor, ought to be able to tell you. There is no reason why they should not be taxed as well as other property.

Wants to Be a Big Bee-Keeper.

I am a boy of 16, and I love to handle bees. I have an apiary of six colonies, and would like to enlarge it to 75 or 100 by next spring. I can buy bees in this county at from 50 cents to \$3.00 per colony in box-hives, and I think there will be a boom in bee-keeping in this part of the country in a couple of years, as the common red clover has gone out of existence, and the famous alfalfa is taking its place. There will be thousands of acres in alfalfa. My apiary is situated on the banks of Big Pipe creek, and its fertile valley will yield acres of alfalfa. The farmers can't get a stand of red clover any more, and almost every farmer has a patch of alfalfa started for seed, and in three years the Big Pipe valley will be all alfalfa. Will the bees work on alfalfa in this country? How can I start a big apiary here? I have the bee-fever, and nothing will stop it but hundreds of colonies of bees.

MARYLAND.

ANSWER.—Alfalfa is grown on a large scale in the West, and many tons of alfalfa honey are secured, but I have never known of its yielding honey anywhere east of the Mississippi. To decide the matter for your locality, wait till alfalfa has been in bloom a few days, then watch to see whether bees are busily engaged upon it on bright, hot days.

If you want to run your six colonies up into the hundreds, it will be advisable for you to gain a full knowledge of the business by carefully studying one or all of the books on bee-keeping you can get, and also gaining practical knowledge by actual work with the bees. By studying a good bee-book you will learn something about the principles of bee-keeping that will allow you safely to take into your own hands the matter of increase if you do not prefer increase by natural swarming. If you want to increase from six to 75 or 100 this year, it should be mainly by purchase. Aside from what you purchase, it will hardly be advisable

for you to increase the six to more than 18, and 12 would be better. Your increase of knowledge and experience should keep pace with your increase in bees, if indeed it does not outrun it, and unless you have had considerable experience with bees it might be better not to increase this year, either by purchase or otherwise, to more than 25 or 50. When you have thoroughly studied your text-book there will be questions arising to trouble you, and it will be a pleasure to help you out in this department.

Any Nectar in Mullen?

Is there any nectar in the mullen-bloom? IOWA.

ANSWER.—I don't know. I never saw a bee at work on it, but it is not plenty where I live.

Requeening by Hiving Swarms.

I have some colonies of bees that are building up slowly, the queens being probably old or inferior. If I remove the queens and in a day or two have a new swarm in with them, would you approve or disapprove of this plan of requeening them? If it meets your approval, would you give them a first or second swarm? PENNSYLVANIA.

ANSWER.—It would probably work all right. Unless the colonies are very small it would be as well to use second swarms.

The Gehring Bee-Veil.

A correspondent writes in defense of the Gehring bee-veil, referring to page 313, and says that he has used just such a veil himself in the hottest days without inflicting punishment on himself, and thinks it "the all-around best for beginners." He says:

"A beginner doesn't want a patent bee-veil, nor an expensive one, nor one that is hard to make, bunglesome to wear, or easily torn when worn among trees and bushes. A veil, the whole of which is made of bobbinet or cape-lace, may do very well for a regular bee-keeper who has clear sailing every day in his well-kept apiary; but it will not do so well for a man or woman needing one only occasionally, and then perhaps in climbing a tree after a swarm. Did you ever try a Gehring bee-veil, Doctor? If not, your criticism is not up to your usual grade."

I may say in reply, that I hardly see why a beginner should not have the same kind of a veil as a regular bee-keeper. The bobbinet veil I spoke of wearing is not patented, nor expensive, it is simpler to make than the Gehring, and it is not bunglesome to wear. I suppose it is more easily torn than cheese-cloth, but I have little trouble with its tearing, even when climbing trees. I do not know that there is likely to be clearer sailing in the apiary of the beginner than in that of the veteran. The beginner in bee-keeping is likely to have his place just as well kept as one who has kept bees for years, and in either case I should rather have a veil that requires care to prevent tearing, than one that would be uncomfortably warm.

No, I do not remember ever to have worn a veil of cheese-cloth. Neither have I ever worn one made of woolen flannel. But I know without wearing a woolen-flannel veil that it would be warmer than one of cheese-cloth. Do you really think I can not know that a cheese-cloth veil would be warmer than one of open lace-work, without actually wearing it? For me the most open veil I have ever worn is a punishment on a very hot day, and I doubt that I am more sensitive in that respect than most persons. So I should not advise the general use of cheese-cloth for bee-veils, either for a beginner or a veteran. If any one is so exceptionally constituted that he will feel no inconvenience on the hottest days from a cheese-cloth veil, by all means he should use the closer, firmer material.

C. C. MILLER.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

THE TRUE HOME THE CORNER-STONE.

I need not say in these "Home Circle" papers—I need not say anywhere, for it surely goes in all our blessed country without saying—that the true home is the very corner-stone in every true society. The best society is builded on its homes. The child that knows no home is bereft indeed. The child that knows not the truest harmonies that alone can make the true home, loses the best that can enter into the life—the soul—of any child.

I dare say I have said all this in other form before. It will bear repetition. I may wisely say it over and over. I hope my readers may take up the song and give it warm, glad utterance. Let us wake in the hearts and minds of all our dear children, the idea of the blessedness of the best home, that we may beget in them an absorbing ambition each day to be the head or centre of the very best home felicity. To this end let me have all your ears to-day as I press the importance of our

SPEECH IN THE HOME.

I am a believer—a sincere believer—in prayer. The man whose life is not braced and anchored in prayer lacks a best help to make his own life superlatively excellent, and his own home what the "Loving Father" wishes it to be. I wish we might all daily pray, "Oh, God, may the words of my mouth this day and ever be such as becometh the gospel of peace." Of course, good words mean a good heart. "Out of the abundance of the heart the mouth speaketh." So we may build onto that prayer, "Create within us a clean heart, oh, God."

I am led to all this by the statement in *Gleanings in Europe* that \$1,059,565,787 is the annual drink-bill of our people. I hope *Gleanings* made a mistake. I fear it is all too true. Oh, friends! is there not a terrible pathos in those figures?

A woman comes to our house each week to help us. She has great energy, has marked intelligence, and has a family of bright, winsome girls. She has had a hell of a home. An intemperate husband is her ill—her terrible—fortune. When drunk he is a very fiend, and no one's life is safe. She loved the father of her precious children. Over and over she received him back as the prison-doors unlocked and let him forth as sentence for repeated debauches expired. At last, in sheer despair, she has, with broken heart, sent him forth to return no more. Who of us that have been saved from such woes and anguish, can possibly appreciate the misery and despair of those hearts and that home? Who of us will not say with deeper anguish, We will do even more to drive that anachronism of our day and civilization—the saloon—from our country? And I wish here to speak of one way.

Do we joke at intemperance? Do we laugh and exclaim in merry mood as the poor, besotted wretch passes us by? Or the rather, does our face sober, and our whole demeanor tell of our sorrow and regret for the fallen soul?

Not long since I was in a Los Angeles street-car. At a stopping, we were brought to face a policeman leading a young soldier in soiled uniform, who was staggering drunk. His maudlin utterance and reeling gait caused almost all in the car to laugh, and even jokes were made at this awful sight. I wondered then—I wonder still—how any one could even think to laugh. *A soul on the down grade!* Or how such a scene could suggest the lightsome word. I rode away sorrowing, and have sorrowed ever since when the picture has returned to memory.

Oh, can we not commence so early to impress our children with the horrors of drunkenness, and the awful evils of the drink habit, that they will not only abhor the saloon and all its vile belongings, but will sadden, and sorrow, and speak grave words, at sights such as I have just depicted?

There is another evil greater than intemperance. It is well called "the social evil," as all others sink before it. Yet who has not seen the grimace, and heard the joke even from lips that claimed to be those of Christian gentlemen? Oh! fellow parents, let us pray, study, think, plan, that we may so culture and refine our dear boys and girls that they may ever walk in ways of cleanness and purity, and that they may sorrow with unutterable sorrow as they become conscious of the ruined, hopeless lives that cloud even our American society. And may never help, by look, word, or act, to add

to the grow-some company that form the sorest blot on our body politic.

CHURCH-GOING.

I hope there may not be too much sermonizing in this manifesto to our homes. Nearly everybody goes to church here in Claremont. The same is true of Pomona. I have heard it stated that over 90 percent of the Pomonaites, including children, are church-goers. Though Pomona has several thousand people, like Claremont she has no saloon. Church-goers and saloons do not flourish on the same soil.

One of our Claremont citizens is a nice man, and has a nice family. His wife always goes to church. She formerly brought all the children. I often remarked to Mrs. Cook, "Oh! that that man could see his mistake." Later the oldest boy ceased to come with the mother. This summer that boy with two others ran away from home. No one knew where they were for days. There was solid grief in those homes. Would not that father, had he gone to church, given the dear wife the richest of comfort? Would he not have been likely to have received inspiration that would have helped him to say better words and do better things before those bright children? Would he not, more than likely, have prevented that sorrowful episode in the home that all felt to be a disgrace?

Now I notice that the second boy is not coming, and only the little girl keeps the mother company. Here, where nearly every one goes to church, how easy to have kept the boys in church and Sunday-school. We have a model Sunday-school in which splendid men and women in prospective are being beautifully fashioned. I truly believe that if our fathers only knew how much such meetings helped to make grand men and women, as well as beautiful and obedient boys and girls, not to say worthy and excellent citizens, they would soon be found of a Sunday morning leading the family to the house of worship. And, oh! how that would rejoice the yearning, longing heart of the mother.

Two years ago I stepped off the train in the great Grand Trunk depot of Chicago. I had written our friend, Mr. York, that I would come on that train. He had written me that I was to wait till he came. It was in the early evening of Sunday. I waited long. It was not tedious. I never am lonely in such places or at such times. The people, some good book or magazine, always make the hours, like birds, fly by. Later our good friend came. He was just from church, where he and his delightful wife always aid in the worship.

God be praised that the old American Bee Journal has a Christian editor, who fears God and desires above everything else to keep his commandments. This fact makes for the refinement and betterment of every reader of our beloved American Bee Journal.

"WILDWOOD APIARY" OF R. V. GOSS.—See page 418.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

To Our Shippers.

About May 1st last, we removed our business from the buildings 120-122 W. Broadway to larger and more commodious quarters at Nos. 265-267 Greenwich St., and 82, 84, 86 Murray St., and we duly sent to our friends in the trade a notice of our removal. Shortly after we vacated the premises (120-122 W. Broadway,) one Joseph M. McCaul, rented a portion of our old quarters, and hung out a sign, "Hildreth, McCaul Co., Jos. M. McCaul, Prop.," with other large signs to the effect that his business is "headquarters for honey, beeswax, maple sugar and maple syrup."

The mercantile agencies report that Jos. M. McCaul is the sole proprietor of the new business, and that he claims to have paid to one Henry P. Hildreth (who has no connection with our business,) a consideration for the use of his name.

We will not comment upon the act of leasing our old quarters and exposing thereon the sign, "Hildreth, McCaul Co.," further than to state that we have instructed our attorneys to apply for an injunction restraining the said McCaul from using the name of "Hildreth" in connection with his business in any manner whatsoever.

We value highly the good name and business we have established by many years of satisfactory dealing with our friends in the trade, and we therefore send this notice so that you may not possibly confound us in any manner with the so-called "Hildreth, McCaul Co."

Our firm name remains as heretofore, and all our business is carried on at our new quarters—

Prospects for a Large Yield.

Bees wintered well throughout this country, and are very strong, working on alfalfa and clover. The prospects are good for a large yield of honey.

The American Bee Journal comes regularly, and is a welcome visitor. W. H. HORN, Santa Fe Co., N. Mex., June 15.

No Nectar in White Clover Bloom.

We have the finest crop of white clover bloom in this section that I ever saw, but there is not a drop of nectar in it, and as this is the only source for a honey-flow at this time the bees are starving. There has been just about enough rain to be seasonable, and plenty of nice, hot, sunshiny days, and it does seem as though everything was favorable, but there is no honey. I would like to ask the reason for this, if any one can tell.

M. D. ANDES, Sullivant Co., Tenn., June 15.

Queens Galore in One Hive.

On Saturday, June 1, I assisted a neighbor, Mr. Balk, in dividing a colony of bees, dividing them as nearly equal as possible, and moving the queen from the hive to a new stand. Yesterday two swarms emerged from the hive on the old stand, one after the other, each having a queen, and all being in the air at the same time without mixing. Immediately after hiving them he examined the hive from which they came, and took from it nine queens, three of which he brought to me. Next.

If there is any bee-keeper who can beat that let us hear from him.

My bees are working on red clover for all there is in it. WM. M. WHITNEY, Kanakake Co., Ill., June 17.

Honey Coming in Fast.

The prospect is for a good honey crop. I have 48 colonies, and 42 of them have supers on filled with clover honey ready to cap. It is coming so fast that I have two supers on some of them to keep them going. I took off two pounds of comb honey and four gallons of extracted June 16.

Sweet clover will be in bloom in a week or two. H. C. FINN, Kane Co., Ill., June 19.

An Aged Bee-Keeper.

Two years ago I had 24 colonies of bees. This year I took eight out of winter quarters, and have had two swarms.

I am in my 80th year, and like the Bee Journal very much. CHRIST BLOTT, Somerset Co., Pa., June 17.

Black Bees vs. Italians.

I expect to stir up a veritable hornet's nest with what I am about to say, nevertheless here goes:

In looking over the advertisements in Gleanings in Bee-Culture and the American Bee Journal, I can not help noticing that everybody seems to be either rearing Italian queens or they are always "the best", or is just about to Italianize common black bees. Now, I wish to make the assertion that the black or brown bee are the best bees for this locality, and for the average person who keeps a few colonies and doesn't pay close attention to them.

In the first place, they always winter better here; and the reason for it is that they have more good, sound, common-sense, and use more judgment, than the Italians, and do not

QUEENS

QUIRIN—THE QUEEN-BREEDER—has now on hand, ready to mail, 500 young, long-tongued Red Clover Queens, Golden or Leather Colored.

We have one of Root's best breeders from his \$200, long-tongued, Red Clover Queen, and a Golden Breeder which we are told is worth \$100, if there is a queen in the U. S. worth that sum.

J. L. Gandy, of Humboldt, Nebr., tells us that the colony having one of our queens, stored over 400 pounds mostly comb honey in a single season. A. I. Root's folks say that our queens are extra fine, while the editor of the American Bee Journal tells us that he has good reports from our stock from time to time.

We have years of experience in mailing and rearing Queens. Queens positively by return mail from now on. Prices for balance of season as follows:

	1	6	12
Selected	\$.75	\$ 4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected tested	1.50	8.00	

Extra selected tested, the best that money can buy, 3.00

try to work in such bad weather as the Italians do, consequently they do not divide so in the spring, and they rear more brood late in the fall.

In the second place, they will enter a super more readily than the Italians.

In the third place, they cap their honey white, and I believe they build their comb just as clean and straight as any bees.

Fourthly, they are much easier to shake off of extracting-combs.

I commenced buying Italian queens four years ago, and have bought about two dozen in all from that time until now, have only one of the lot left alive to-day, and she is a complete failure. They have had as good a success as the blacks in every respect, and were bought from different breeders, all the way from Texas to the State of Michigan.

If any queen-breeders take exception to this, all right; but I am through buying Italian queens.

Geo. B. WHITCOMB.
Linn Co., Ore., June 13.

Experiences of a Beginner.

Last fall I went to an auction sale where there were a few colonies of bees for sale, and bought one colony for the small sum of \$1.00. I wintered them in the cellar with another colony which we kept in the woods, keeping the temperature at about 55 degrees.

This spring I went to a bee sale where there were about 45 colonies to be disposed of. I bought the first five at \$2.00 each, but when I got them home the next morning I found I had only four colonies and one empty hive.

They are doing very nicely now, and have thrown off the swarms which we managed to live in good condition. The first swarm issued June 5.

White clover has been in full bloom for about a week, and red clover is doing well.

I like the American Bee Journal very much.
JOHN B. CALDWELL.
Winnesbick Co., Iowa, June 17.

Outlook for a Fair Honey Crop.

Last March we moved our bees from Fund du Lac County to Richland County, there being but little bee-pasturage in the former county, and the locality was also overstocked, consequently they have had but two fair honey crops in the past 10 years.

There is a good outlook for a fair crop of honey in Richland County. It has been quite cool all spring, and consequently not much up yet, but, but we are having warm days and nights now, with a little rain about once a week, and there is more clover bloom than there has been in the past two years. Brood-chambers are filled with honey, and the bees are working in the supers. Practically all bee-keepers here are working for extracted honey, we being the only ones working exclusively for comb honey.

ALBERT REIS.
Richland Co., Wis., June 18.

Good Report from Michigan.

Michigan is to the front again with a large honey-yield. Last year my colonies averaged 120 sections each of comb, and 15 pounds each of extracted honey—the finest I have ever tasted. And now, notwithstanding the late spring, it bids fair to outrank last year.

I did not remove the winter packing until June 1, on account of the cold weather. The bees had a hard struggle to feed the young brood up to that time. June 3 they cast their first swarm—one day earlier than last year. In just one week this young swarm had seven brood-frames filled with honey and brood, and that without comb foundation being furnished them. To-day they have 11 brood-frames filled, and 30 queen-cup-sections. The old colony cast the second swarm—larger than the first—on June 13, and has filled 26 one-pound sections besides. My largest colony—that is, it seems to be the most populous—has not swarmed in two years, but it has filled 76 one-pound sections since June 3, and has put 74 more to-morrow. I do not know where they procure the honey, as I have not had time to investigate. There is

white clover in abundance, but I have failed to see the first bee on its blossoms this year.

I am not using comb foundation this season, but have a much better and cheaper device, which I will describe later.

D. H. METCALF.
Calhoun Co., Mich., June 17.

Weather Hard on the Bees.

I had 18 colonies of bees, spring count, but two of them were very weak, and have since died.

The weather this spring has been the most unfavorable for many years. April came in cold, rainy and cloudy, with only 53 hours of sunshine the whole month. May was a little better, there being only 67 hours of sunshine, and very cold. Apple-bloom first appeared May 21, and May 23 it commenced to rain, and continued cold and rainy, the bees having only one day in which to work on it. The weather has been very fine for the past two weeks, and although I can not see from what source they are gathering, they are storing honey very fast.

I have had only five swarms so far this season, but they are working hard, having just started in the sections.

Basswood is very scarce here, but there are hundreds of acres of raspberry and white clover; also goldenrod in great quantities.

I find many useful hints in the Bee Journal.
T. R. WEBSTER.
Cheshire Co., N. H., June 14.

Bees Working on White Clover.

There is an abundance of white clover, and bees are doing fine. We have had only one swarm, but have divided four colonies.

Some of the colonies have the third super nearly full of honey.
C. A. FAIRBANKS.
Jones Co., Iowa, June 17.

Bees Rolling in the Honey.

My bees are just rolling in the honey now, and it keeps me busy with new swarms. I have 70 colonies in all.
D. E. LANE.
Washtenaw Co., Mich., June 16.

Do Bees Select Their Future Home Before Swarming?

We are all interested in anything pertaining to the habits of our bees, even if it does not have a commercial aspect; and any one having a new fact, or who can explain an old one, is contributing something of value to natural history. Hence, the question of bees selecting their future home before swarming is not altogether without interest. Prof. Cook thinks they always do, and mentions having seen scouts investigating a cornice on a building, and the next day a swarm took possession.

I had the temerity to question the statement that they always select their home before swarming; Mr. O. B. Griffin, of Maine, on page 141, thinks that, "in the majority of cases," they do not. And now comes Mr. D. H. Metcalf, of Michigan, who thinks (page 157) that "first swarms always do two instances of swarming never," and mentions two instances of swarming "scouts" (I believe an old scout, call them) investigating a bee-tree, and one where the swarm actually came and would have taken possession only he had felled the tree. This looks pretty solid, on the face of it, for the affirmative side of the question, and yet it is only what the lawyers would call a "prima facie" case. I first saw an instance. Mr. Metcalf had seen the swarm issue, and followed it up to the bee-tree, the chain of evidence would be more complete; but I would ask in this case, as I did in the one mentioned by Prof. Cook, Have you any evidence to show that the swarm was not already clustered somewhere at the time the scouts were sent? This will cover the whole point of contention.

I would like to ask the fundamental question. Why does a swarm cluster at all? There would be no need of it if they had already selected their home. Prof. Cook says, "To rest the queen." I can't think the Professor was serious when he made that statement, for if bees have as much sense as they

are usually credited with, they would certainly know that a flight from the hive even to the top of a tall tree (possibly from 100 to 300 feet) would not tire an old queen with perfect wings. If swarming bees or queens ever do get tired it is more reasonable to suppose it would be after they had started on their journey to a home, and maybe they do; but to "stop to rest before they are tired!"—well, I can't see the sense in it.

In conclusion, I do not think bees select their future home before swarming, for the following reasons:

First, 99 percent of all swarms cluster a certain amount of uncertain time before leaving. We have no definite information on the subject, as most observed swarms are bived as soon as possible by the bee-keeper; but in most cases it is from one hour up to 72. Bees fly very rapidly—I think I am within the limit when I say a mile in three minutes. There is ample time for a thousand scouts to explore and report every possible bee-tree within five miles of the cluster inside of an hour. Second, the uncertainty of the time in clustering indicates to my mind the greater difficulty in one case over another, in finding the future home, and the greater probability that they, like some human beings, do not cross a bridge until they come to it, or do not select a home until there is strong need of it.

This is my view of it. But I'll change my mind any time the weight of evidence is the other way.

COOK CO., Ill.

RIP VAN WINKLE.

Drone-Traps.

W. H. Bridgen says in the American Bee-keeper:

In using the combined queen and drone trap on hives that are sending out objectionable drones, I usually have trouble in separating the queen from the drones in case a swarm issues, without allowing the escape of many drones. This can be overcome by a double or combined trap. There should be a division made of drone-excluding zinc through which the queen can freely pass, with an additional trap with ordinary cone above, to catch the queen. That is, to separate the queen from the drones, we want two traps, one above the other, with the slide in the top of the drone-trap, with perforations large enough for the queen to pass through without allowing the drones to do so.

Cost of Drone-Comb.

Probably the majority of bee-keepers discourage the presence of much drone-comb. Just as probably the majority have a good deal more drone-comb than is profitable. The bee-keeper who has supplied his bees with full sheets of worker foundation is not safe for all future time. Here and there a mouse will nibble a hole in a comb in winter, and by one means and another there will be holes that the bees must fill in, which holes will almost invariably be filled with drone-comb. If no attention is paid to the matter this will increase from year to year, but the bee-keeper perhaps gives it little thought. If his attention is called to it, he will say, "Yes, there is some drone-comb in most of my hives that have comb of any age, but it doesn't amount to much. There isn't an average in each hive of more than enough to fill a pound section."

Let us figure up the cost of a piece of drone-comb of that size—4 inches square, or 16 square inches. Counting 18 cells to the square inch, or 30 for the two sides, 16 square inches will contain 576 drone-cells. Suppose only one brood of drones is reared, and that each drone lives 60 days; what will be the cost of those 576 drones? Taking the estimate that it costs .0141 ounce of honey to rear a drone, and that it consumes .0025 ounce of honey daily, it will consume in 60 days .384 ounce of honey, which, added to the cost of rearing,

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet imported. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

Please Mention the Bee Journal when writing Advertisers.....

makes .3951 ounce of honey that each drone costs. Multiply this by 576, and you have 227.5776 ounces, or 14.2236 pounds of honey that has cost to produce the same amount of honey that that piece of comb the size of a pound section.

"But," you say, "I don't stand all that expense, for I slice off the heads of the sealed brood every time I go over them, so I stand only the trifle that it costs to rear them."

Suppose we figure on that. Multiply .0414 by 576, and you have 23.826 ounces of honey that each slicing has cost you. Remember that this cost has occurred before the cells are sealed; and as fast as you slice off the heads of the brood a fresh lot will be started so long as there is a moderate degree of storing. Suppose you begin slicing June 1, and slice every seven months, making the last slicing July 13. That will make four times, costing you a trifle more than two pence. Don't you believe you could go over 25 colonies in a day, cutting out the drone-comb and putting patches of worker-comb in place thereof? That would give you a payment of 50 pence of honey for the day's work, to say nothing of the saving in future years. *End of the drone-comb.*—Gleanings in Bee-Culture.

A New Bee-Keeping El Dorado.

It is in Arkansas, and L. E. Kerr says in the American Bee-Keeper:

The flow begins here the first of April and continues till November. It is not spasmodic, but comes in a slow, steady stream for about seven months, enabling a wide-awake bee-keeper to secure from 100 to 300 pounds of comb honey, of first-class quality, as an average yield per colony.

With a honey-flow lasting seven months many would naturally suppose that the matter of keeping the colonies in shape to do the best work would be no little item; but really all we have to do is to keep our queens and let them alone, and they remain strong themselves, with no swarming except during April and May.

Editor Hill comments as follows:

"From 100 to 300 pounds of comb honey of first-class quality, as an average yield per colony," is truly wonderful. In this day of small yields, it is refreshing to read of such a locality. Mr. Kerr's idea, as to the superior finish and quality of comb honey where the bees have seven months to devote to the work, is something entirely new and quite at variance with the experience of nearly, if not quite, all experienced producers of comb honey. We should decidedly prefer a location where all the finish and trimmings were applied in ten days. It is a magnificent theory, indeed; but we have never learned to admire "a slow, steady stream," when "first-class" comb honey was the object.

Long Tongues and Their Value.

Dr. Miller thinks long tongues may be of value for other blossoms than those of red clover, but that longest tongues are not necessarily best in all cases. He says in Gleanings in Bee-Culture:

Why should it be considered a strange thing that other flowers should have tubes of the same depth as red clover? It is possible that many of the flowers commonly visited for nectar have tubes of different lengths, some of them accessible only to tongues of unusual length, thus giving long tongues the advantage aside from red clover. Again, a flower-tube may be of such depth that only part of its contents can be reached by a tongue of ordinary length, while one a little longer may drain it to the bottom.

Please don't understand that I believe that length of tongue is the only thing to be considered. I should prefer to make selection by noting the amount of stores gathered rather than by measuring tongues. It is possible that among several colonies, the one with the longest tongues may be the poorest. One colony may excel it because of greater diligence. Another may work earlier in the day. Another may excel because of greater longevity. So

I think it would have been unwise to depend upon tongue-length alone. But I do insist that the advantage of long tongues has not been proven to be exclusively associated with red clover; and it is possible—not probable, I think—that the gain from other flowers with long tubes may be even greater than from red clover.

Straining Extracted Honey.

Elias Fox gives his plan in Gleanings in Bee-Culture as follows:

I have six large barrels, holding about 600 pounds each, arranged around my extracting-room on a strong bench, with heads out, and molasses-gates near the bottom. Each barrel is supplied with a fine cheese-cloth strainer tied securely over the head. I draw the honey from the extractor into an ordinary water-pail, and transmit to these barrels through the strainers. This takes out the minute specks. It is left in these barrels from one to six weeks (according to the time in the season of extracting), when it is drawn off into 60-pound cans, caps screwed down tight, and placed in cases, and securely nailed, ready for shipment. I have practiced this method for the past 18 years, and have never had a word of fault found.

UNTESTED

Italian Queens Free

BY RETURN MAIL.

For sending us One New Subscriber for one year, to the American Bee Journal, with \$1.00, we will send, by return mail, a fine Untested Italian Queen free as a premium. This offer

is made only to our present regular subscribers.

We will mail one of the above queens alone for 75 cents; or 3 for \$2.10.

Please do not conflict the above offer with the one on another page which refers to Red Clover Queens. For sending us two new subscribers, and \$2.00, we will mail free as a premium an Untested Red Clover Italian Queen.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 19.—New comb honey has not yet reached the market. It would cost at least 10c if choice white, and the ambers at 12 to 13c. The market is entirely bare with exception of a few cases of a lot that we had held for us, expecting it would be needed. Advertisers are that shipments will be started by July 1. Very little trading is being done in extracted, as large dealers will not contract this season unless at home at such prices as some of our salesmen have made at 4½¢ to 5c for early autumn delivery; white is held at 5c. Beeswax sells at 30c.

R. A. BURNETT & Co.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from ½ to 1 cent per pound.

C. H. W. WEBER.

BOSTON, June 14.—There is practically no comb honey in our market, and owing to warm weather very little call for it. Are expecting some new comb early next month. Market for extracted dull, at 9½¢ to 75c.

BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00.

PEYCKE BROS.

NEW YORK, June 1.—Extracted honey is exceedingly dull and very little moving. We quote for the present: White, 6½¢ to 7c; light amber, 5½¢ to 6c; amber, 5c to 5½¢. Some demand for comb honey at such prices as some of our salesmen are beginning to arrive from the South, and sells at from 12 to 15c, according to quality and style. Beeswax, 2½c. HILDRETH & SGOELKEN.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts of stocks and little demand. It is between seasons now. Prospect of good crops in this section from what bees there are left, the greater portion having been killed by foul brood exterminators. H. R. WRIGHT.

DETROIT, June 24.—Very few sales of honey, but prices are well sustained on good lots. The new crop will start out at good prices, and with little old honey to interfere. Beeswax in fair demand at 27 to 28c. M. H. HUNT & SONS.

BUFFALO, June 26.—Honey not wanted till cool, fall weather. Little old honey here and dragging, 9 to 10c. Extracted not wanted. Fruit takes place of honey now. BATTERSON & Co.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being granulated. Sales light at 15 cents for best grade No. 1 Colorado. Amber, 13c. Beeswax firm at 25 to 26c.

W. R. CROMWELL PRODUCE Co.,
Successors to C. C. Clemons & Co.

SAN FRANCISCO, June 5.—White comb, 11½¢ to 12½¢; amber, 10 to 11c; dark, 9 to 10c. Extracted, white, 5 to 6c; light amber, 4 to 4½c; amber, 3½ to 4c. Beeswax, 26 to 28c.

Dealers are very barish in their ideas, but are not securing much honey at the prices they name. In a small way to special trade an advance on quotations is being realized.

At the Pan-American

I can accommodate five or six persons who wish to attend the Pan-American Exposition. Rates reasonable. Good car service half a block away. If any wish to engage rooms in advance, address,

A Bee-Keeper's Paradise.

En route to El Paso.—I have just come from a county about
40 miles square that has more bee-keepers to the square mile than
any other locality of its size I ever visited. The inhabitants talk
bees at the hotels, on the streets, and everywhere, just as farm-
ers talk crops and business in the North. This county produces
more honey than any equal area, I believe, in the United States.
Some say that its yearly output is a whole trainload of honey; but
many aver that this is too low, and that two whole trainloads
would come nearer the truth. Of course this great amount doesn't
go all in one lot, but in large and small shipments.

The average per colony is high, and there is a honey crop
every season. It is estimated that in this one county, outside of
the towns, nearly one-half the population are bee-keepers.

The great bulk of the honey is of the very finest, and some of
it is literally water-white. There are thousands and thousands
of acres of honey-plants on cheap land: and bees—there are not
enough to gather it all.

The bees commence swarming early in the spring; and, when
the main honey-flows commence, actually stop swarming, destroy
cells, kill off the drones, and commence business. Did you ever
hear the like of it before? You say, "No, and no one else."
Well, I think I can prove every statement; but for the present I
am not at liberty to give the place or other details; but very
shortly I'll tell the whole story, with some fine pictures.

This is only one of the good things in store for readers of
Gleanings in Bee-Culture. Send 15 cents for three months' trial
or 25 cents for six months' trial, or \$1.00 for one year and one un-
tested Italian Queen. Send \$2.00 and we will send Gleanings one
year and one of our Red Clover Queens. Speak quick if you want
one.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation that started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 4 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

HOT WEATHER HINT.

"Hot weather! yes; but really not Compared with weather twice as hot. Find comfort, then, in arguing thus. And you'll pull through victorious: For instance, while you gasp and pant And try to cool yourself—and can't— With soda, cream, and lemonade. The heat at ninety in the shade— Just calmly sit and ponder o'er These same degrees, with ninety more On top of them, and so concede The weather now is cool indeed!"

—J. WHITCOMB RILEY.

MR. C. A. HATCH, writing us June 22, had this to say:

"We had poor luck in wintering bees the past winter, so we have not an extra-large force of honey-gatherers. I think fully 50 percent of the bees in this part of Wisconsin are dead. My own loss was about 30 per cent—the heaviest for many years. We hope for better luck next time."

DR. A. B. MASON, secretary of the National Bee-Keepers' Association has been appointed judge of the bee and honey department of the Ohio Exposition, which will be held at Columbus next month. A total of only \$74 is to be awarded in that department, so the Doctor ought not to have a very long or hard job.

The Doctor wrote us, July 1, as follows about his bees:

"No honey from the world of white clover we have, but sweet clover is getting nicely in bloom, and the bees are busy on it. We have colonies with two, three, and three and a half stories, to give room to the bees, and running over at that, and no disposition to swarm."

MR. W. W. WHITTLE and his apiary, of Arapahoe Co., Colo., are shown on our first page this week. Mr. W. is a native of Michigan, and in his boyhood days learned the printing business. He drifted into western Iowa in the early fifties, and went to Colorado in 1859, during the Pike's Peak gold excitement. He has worked as printer, job printer, miner, and lastly as a bee-keeper, and will probably follow the latter occupation the remainder of his days.

Mr. Whittle has met with varied success in bee-keeping, but is fairly well satisfied, although he says the bee-keeper has no picnic in Colorado. He must be constantly on his guard to keep clear of that pest—foul brood. When he first went to his present locality there were many farmers who had a few colonies of bees, and when a colony died they would not know the cause, or even that it was dead, and in most cases it was foul brood that killed it, until the colony was robbed of its stores, and they were spread far and near, making trouble for the bee-keepers. Bee-keeping there would be a pleasant and profitable business were it not for this, so Mr. Whittle says.

They are expecting a good alfalfa honey season this year, as the crop of alfalfa is very forward and seems likely to bloom abundantly. He expected the flow to be on about June 20, when there would be busy days, and the "hum of the bees in the alfalfa bloom" could be heard on all sides.

The Bee-Keeper's Guide;

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to date. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without **THE BEE-KEEPER'S GUIDE**.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting **NEW SUBSCRIBERS** for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to **PRESENT SUBSCRIBERS** only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year.

Send us two **NEW SUBSCRIBERS** to the Bee Journal (with \$2.00, and we will mail you a copy of Prof. Cook's book **FREE** as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only **TWO NEW SUBSCRIBERS** to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

THE OLDEST BEE-PAPER IN AMERICA

41st YEAR.

CHICAGO, ILL., JULY 11, 1901.

No. 28.

* Editorial. *

Are You a Member of the National Bee-Keepers' Association? If not, you should be. But perhaps you would like to know more about it before becoming a member. If so, write to the general manager, Mr. Eugene Secor, Forest City, Iowa, for circulars explaining the objects and work of the Association.

You will remember that last week we began the effort to secure a membership of an even 1000 by the time of the Buffalo convention, in September. Send in the dollars for dues, so we can begin to publish the list of names. We want to receive over 200 during July and August.

Are you a member of the Association?

The Buffalo Convention.—We have received the following notice and information in reference to the next meeting of the National Bee-Keepers' Association at Buffalo:

STATION B, TOLEDO, OHIO, JULY 1.
MR. EDITOR:—Please say in the American Bee Journal that the next convention of the National Bee-Keepers' Association will be held in the Lecture Room of the Buffalo Society of Natural Sciences, on the 10th, 11th and 12th of next September, commencing on the evening of the 10th. The place of meeting is in the Buffalo Library Building, corner of Washington and Clinton Streets, near the business center of the city.

Railroad rates will vary in the different passenger association territories from one cent a mile each way to one and one-half for the round trip. Each one can readily learn the rate on enquiry at his or her railroad station.

The Buffalo bee-keepers will try to provide entertainment at reasonable rates for all attending the convention who will notify Mr. Sidney S. Sleeper, Holland, N. Y., by Sept. 2. In a letter recently received from Mr. Sleeper, he says:

"We want all who can to come, for we wish to make the Buffalo meeting the most pleasant and instructive one that has ever held in America. We will have the co-operation of all the sciences, as well as the school board; then he names some professional men who are interested in our specialty, and will be at the convention to help; and a long letter from Mr. Hershiser closes by saying, 'Call upon me for whatever further assistance I am able to render,' and Mr. Penton, an ex-president of the Erie County Bee-Keepers' Society, and others, have promised to do all they can to provide for the comfort of the delegates.

As stated in my previous convention notice in the American Bee Journal, there will be no fixed program, and no papers, the time being fully occupied in asking, answering, and discussing questions, except that on the evening of the 12th there will be a joint session of our

Association and the American Pomological Society, to discuss 'The Mutual Relations of Bee-Keeping and Fruit-Growing,' and Prof. Beach, of the New York Agricultural Experiment Station, and Prof. Fletcher, of the Central Experiment Farm, of the Dominion of Canada, will help talk for the bees at that session. It is hoped that much good will result to fruit-growers and bee-keepers from this joint session.

If any bee-keeper who can not attend the convention has any questions he would like to have answered at the convention, will send them to me. I will see that they are presented. I made this same request in my previous convention notice in your journal in April last, and perhaps you'll remember of writing me to the effect that with such a request in all the bee-papers I would be deluged with questions, and in the last week's American Bee Journal you talk very nicely editorially on the same subject, and still I've not received a single question, except about 20 I've sent myself, and I have several more in my mind that I'm going to send to the secretary.

A. B. MASON, Sec.

In-Breeding, as treated by C. P. Dadt in this journal, seems to puzzle Deacon Hardscrabble, a bright writer who has suddenly appeared in the horizon of the American Bee-keeper. He is confused at the two statements that nature abhors in-breeding, and that "in natural conditions a colony may be several miles from other bees and probably requires all the drones that it may produce." You didn't notice that "may be," Deacon. You know there are exceptions to all rules, and nature doesn't in all cases find things to her liking. She'll remedy that by planting a colony at next swarming-time between the two distant colonies, so that the drones can pass the distance between.

Several Laying Queens in One Hive.

—Swarthmore says in *Gleanings in Bee-Culture* that the secret of success in having several laying queens kept throughout the season in one hive, lies in the giving them all at one time to bees that have been queenless for but three days. "An indefinite number of queens may be confined in boxes or cages arranged in such a way that none can come in contact, yet allowing the bees freedom to go and come, to do as they will."

Watercress Honey.—W. A. D. Pen reports in the British Bee Journal that he gets quite a quantity of honey of very good quality from watercress bloom. He says the bees store very fast from this source, and will fill a super in a few days. We have never heard of watercress yielding honey in this country. Perhaps some of our readers can report it. We understand that watercress is shipped to Chicago by the barrel, being used as greens.

The Illinois State Fair premium list for 1901 is now issued. A copy of it can be had by addressing W. C. Garrard, Secretary, Springfield, Ill. It will be the 48th annual exhibition, under the auspices of the Illinois State Board of Agriculture.

Under the heading, "Bees and Honey," we find the following list of premiums offered, which are "open to the world."

	1st	2nd	3rd
	prize	prize	prize
Display of comb honey.....	\$20	\$15	\$10
Collection of labeled cases containing 12 or more pounds of white honey from different flowers....	8	5	3
Collection of labeled cases containing 12 or more pounds of amber or dark honey from different flowers.....	8	5	3
Case white clover comb honey, 12 to 24 pounds.....	4	3	2
Case of sweet clover comb honey, 12 to 24 pounds.....	4	3	2
Case basswood comb honey, 12 to 24 pounds.....	4	3	2
Display extracted honey.....	20	15	10
Honey extracted on the ground.....	5	3	2
Frame of comb honey for extracting.....	5	3	2
Display of candied honey.....	20	15	10
Display of beeswax.....	15	10	5
One-frame observatory hive dark Italian bees.....	4	3	2
One-frame observatory hive Golden Italian bees.....	4	3	2
One-frame observatory hive Carniolan bees.....	4	3	2
Honey-vinegar, 1/2 gallon, with recipe for making.....	4	3	2
Display of designs in honey or beeswax.....	12	8	6

The judges will be governed by the code of rules adopted by the Illinois State Bee-keepers' Association.

500 pounds will receive full score for quantity in displays of comb and extracted honey, and 200 pounds in displays of candied honey. 50 pounds will receive full score for quantity in display of beeswax.

Only one entry will be allowed for each exhibitor for any one premium.

There is over \$300 offered to bee-keepers in the above list. For some years there have been very creditable apianian exhibits at the Illinois Fair, and we trust that this year will be no exception. All who can possibly arrange to do so, should begin to plan to make an exhibit.

The State Fair will be held at Springfield Sept. 30 to Oct. 5.

Hot Weather for Honey.—Editor Root says that in the Salt River valley, Arizona, the bee-keepers want the heat to be from 95 to 110 in the shade to get the best results in honey storing. When the temperature is below 90 there is quite a perceptible decrease in the inflow of honey. "Apparently," he says, "the Arizonians want more heat than we of the North. Yet the hottest days, and the hottest nights, seem to be the best in the North for a big flow."

Storing Comb Honey and Surplus Combs.

BY G. M. DOOLITTLE.

A CORRESPONDENT wishes me to tell, through the American Bee Journal, how I would fix for storing comb honey and surplus combs in some building already on a new place he has just moved to, he wishing to make what changes are necessary. As I quite frequently have this question or similar ones asked, I will gladly comply with the request.

For a honey-room the first thing necessary to know is that there is a good foundation under that part selected for the room, and sleepers of suitable strength, so that should we happen to place several tons therein, there will be no danger from breaking down. Knowing this, the next thing is to make the room mouse-proof. This I would have, let it cost what it would, even if I had to line every inch of it with tin, for the filth from vermin about honey is not to be tolerated at all. Having the room mouse-proof, all that is necessary afterward is to be sure the door is kept shut when not in use.

It is better to locate this room in the southwest corner of the building, and paint the outside of the two walls which come next to it, black, or some very dark color, so that the rays of the sun may be so absorbed as to heat the honey-room as much as possible, as the hotter and dryer the honey can be kept, when off the hives, the better it will ripen and keep afterward.

The door to the room should be on the side nearest the general entrance to the building, so as to save as much travel and lugging as possible. Then there should be two windows in the room, one on the south and one on the west side, which are to be opened on warm, dry days, so as to ventilate thoroughly the room and pile of honey. Over these windows, on the outside, is to be placed wire-cloth, so the windows can be left open at pleasure, without any fears of robber-bees. To let the bees out, which may chance to come in on the honey or in any other way, let this wire-cloth run eight or ten inches above the tops of the windows, nailing on strips of lath, or other strips $\frac{3}{4}$ thick, so as to keep the wire-cloth out that far from the sides of the building, thus giving space for the bees to crawl up on the cloth to the top when they are on the outside. With me, no robber-bees ever think of trying to get in at this entrance, their efforts being directed toward the open window, where the fresh scent of the honey comes, and, by so fixing, your room is kept clear of bees, flies, and other insects all the while.

In hanging the door for this honey-room, do not make the mistake that some do, of having it swing into the honey-room, for if you do you will regret it some year when you have a bountiful crop of honey, as it will be greatly in the way at such times, and more or less at all times. Let it swing out into the main building, and hang it so that when you wish, it will swing clear around against the side of the room, thus being entirely out of the way.

On either side of the room fix a platform for the section honey, which should be at least six inches above the floor. This platform should be built nearly as solid as the floor has been, and should be so arranged that the air can circulate up between and around each section or tier of sections. Or if you store the honey away in the supers, then, no matter what style of super you may use, this platform is to be so arranged, that each super is separated from its neighbor an inch or so at the bottom, top, and all around, so that the air can circulate all through and all about the honey, thus curing and ripening it thoroughly. Many fail here, and after working hard to produce a crop they let it deteriorate from one to three cents a pound in not properly caring for it after taking it from the hive. And not only that, but such poor honey generally bought cheaply, injures the market to quite an extent for others. When fixing it costs little more to have it so your crop is always growing better, instead of becoming of less value, and after once fixed, the labor required for universally sending off a good article is not so great as it is to fix up that which has partly spoiled after its production.

Then you wish your honey stored and piled as above, so

that the fumes of burning sulphur, or something of a similar nature, can penetrate the whole pile, should it be necessary to fumigate on account of the larvae of the wax-moth being liable to injure it. Don't be afraid of a little extra work or expense in fitting up this room, for on it hangs as much of your success as the producer of fine comb honey, as on any part of the pursuit.

And now about the room or closet for all frames of comb not covered by the bees, or not in use in the hives. In some convenient place, on one side of the building, spike on 2x4 scantling, just as far apart as the top-bar of your frame is long, using as many of these as you think you will ever have use for. Now nail strips of stuff, 2½ feet long by five inches wide to these studs, letting them stand out into the room in a horizontal position. Let the distance between each strip from top to top be two inches greater than the depth of your frame, so as to give sufficient room to manipulate the frames handily. Three inches from the ends of these strips run a partition clear across the space occupied for the purpose of storing these combs, which partition is to have close-fitting narrow doors placed in it, spaced so as to be most convenient. Close up the ends, and see that top, bottom, ends and sides are as nearly tight as possible, so that in fumigating there shall be as little waste of the gases as may be.

Now hang in the combs whenever you have any not occupied by the bees from any reason, and see that all combs not in use are in their place, and not lying about somewhere else. As often as any signs of worms are found, put in a pot of burning sulphur, close the doors, and the work is done.

Is a \$200 Queen a Fake?—Queen Values.

BY DR. C. C. MILLER.

ON page 391, G. M. Doolittle has gone beyond anything I have seen in print in showing that there may be justification in placing a very high price upon a queen. Granting his premises, the extra 10 pounds of honey and the 4,000 queens, it is hard to get away from his conclusion that "we have \$3,750 as the worth of that queen."

Coupled with that is a repetition of the strong intimation on page 293 that the A. I. Root Co. are in the fake business when they advertise that they have a \$200 queen. Mr. Doolittle refers to it as being like the work of a fakir, and says a fakir is a "street vender." Looking at the dictionary I find that a *fak-er* is a street vender, and a *fak-ir* is "one who originates a fake, humbug, or swindling contrivance." Mr. Doolittle's line of argument is somewhat hazy, but clearly discernible through the haze is the intimation of dishonesty on the part of the A. I. Root Co.

Mr. Doolittle makes the rather strange assertion, "There is no value in a dollar." If that be true, then there is no value in \$200, and he should hardly find fault with attaching to a queen a price of "no value." But he seems to object to a queen "having only a dollar-and-cent value attached to her," and says, "the simple saying that this queen 'is worth \$200' without any qualification.... expresses no value, save that which comes from the wear and tear of the lungs doing the hawking." Elsewhere he says, "But not to appear as a fakir, we should know that the queen has *real value* in the work accomplished by her bees and those from her queen daughters, putting that *work* out to the world as her real worth, rather than saying that 'we value her at so many dollars.'"

It is not entirely clear just what it is to which Mr. Doolittle is making objection, but it sounds a little as if he were objecting to placing upon an article a value in dollars and cents. Surely he can hardly object to a thing which is absolutely necessary to the transaction of business, and without which the wheels of commerce would stand still. Mr. Doolittle himself puts a dollar-and-cent price on the queens he sends out. O. L. Hershiser told me he got a queen from Mr. Doolittle that Mr. Doolittle said was worth \$50 to a breeder. What wrong was there in that? The dollar is the unit of value, and there is no other way by which he could in so few words express the value he placed upon that queen than to say how many dollars she was worth. And if it was right for him to say she was worth \$50 because her progeny were beautiful (I saw them, and they were beauties), is it wrong to say another queen is worth \$200 if she really possesses such value? Again, on page 380 of the American Bee Journal, H. G. Quirin advertises a Golden Breeder from Doolittle, saying that Doolittle says, "If there is a breeder of golden bees in the U. S. worth \$100,

this one is worth that sum." Notwithstanding the condition attached, there is the value "at so many dollars."

There seems no impropriety in the universal custom of naming values in dollars and cents, the only question being whether the article is really worth the price named. The fact that some one else may lyngly say he has a queen worth \$1000 when she is not worth one-tenth of that sum, although it may have some bearing upon the policy of the case, has none upon its honesty, and it is the honesty rather than the policy of the A. I. Root Co. against which Mr. Doolittle is training his guns.

If he thinks \$200 is too large a valuation for the queen in question, he has a right to say so, and to show cause why it should be lowered. That valuation appears to be based upon length of tongue and increased harvests. Taking Mr. Doolittle's figures and using a simple proportion, we have \$3,750 is to \$200 as 10 pounds is to 8 $\frac{1}{2}$ ounces. So according to Mr. Doolittle's estimate, if 4000 queens are reared from the queen in question, and one out of four of them makes an increase of a little more than half a pound in the annual harvest, then \$200 is none too high a valuation to place upon such a queen. McHenry Co., Ill.

Co-operation—What it Has Accomplished for Our Bee-Keepers.

Read at the Longmont meeting of the Colorado State Bee-Keepers' Association, April 30, 1901.

BY W. L. PORTER.

I PRESUME there are few bee-keepers present who have not been thinking of a plan by which we may sell our honey and buy our supplies in a co-operative way. The fact that we are so far from markets in the East, where our honey is to be sold, makes it quite necessary that we should sell our honey in a combined way. Freight is so high that we must ship our honey in car-load lots.

Over two years ago the State Association called a special meeting for the purpose of organizing a co-operative association. On investigation it was found that, to do business under the statutes of Colorado, it was necessary to form a stock company. Hence the bee-keepers organized themselves into a stock company with a capital of \$10,000, a share being \$10. It was voted to name this "The Colorado Honey-Producers' Association." A constitution and by-laws were adopted and the Association was incorporated in January, 1899.

Before co-operation was entered into, the tendency was for the price of honey to be lower each year. For ten years I have noticed this to be the case, so that in 1897 I was compelled to sell my crop of fine honey at \$1.70 for 24-pound cases. At this time the Denver Bee-Keepers' Association decided that something must be done to better this condition. We advanced a small sum of money and one of our number opened a correspondence with parties in the East. At the same time we pledged our honey, provided we could get the purchaser to come on and examine the honey and pay cash on delivery, if satisfactory. We were successful in getting buyers to come on and we sold our honey in the far East at better prices than we could otherwise have realized.

The Colorado Honey-Producers' Association, upon opening for business, found it a difficult task to get the honey together, as it was very much scattered through the country, and we at once saw that it was necessary to have a warehouse, and a room was rented. The first year, the manager was at the warehouse two days in a week to receive the honey, and it was brought and placed on deposit, a receipt taken for the same, and the honey was kept fully insured. There was some opposition from the commission-houses, as they thought we would have all the honey-business and leave them out. But at present they are very friendly, as they say the price of honey is more stable since we have organized. They see that it is a real convenience, when they have a jobbing order to fill, they know where they can get the honey to fill it, and can see the honey displayed, and get just what they want.

At this time it was hard to make many of the bee-keepers understand that it would be to their advantage to sell through the Association. They were also skeptical as to receiving any rebates.

Perhaps it would be well for me to explain here that at the first meeting of the Association, it was voted that one-half of the dividend should go to the stockholders, and the other half to be divided pro rata per case of honey. This was found to be an unjust division as some of the stock-

holders did not sell any honey through the Association. Yet when the adjustment was made the man who had a ten-dollar share got \$8.50 dividend. So at the annual meeting, 1900, the by-laws were changed so that Sec. 10 reads:

"Any surplus money accruing over and above the expenses of the Association shall be divided as follows:

1. A dividend of one dollar shall be paid on each share of stock issued.

2. All surplus money remaining after said dividend has been declared shall be related to the stockholders in proportion to the amount of commission paid by them during the year, said dividends and rebates to be paid only to those who have become stockholders previous to August 1 of the year in which surplus accrues."

As you will see by this plan, it is to the stockholder's interest to sell as much of his honey crop through the Association as possible, as by so doing it would not only increase the volume of the Association's business, but also insure him a large share of the rebates. As a consequence, the past year's business of the Association was greatly increased and the rebates covered nearly all the commission charged, so that the members had their honey stored in a proper place where it was always on display, insurance was carried on the honey while in storage, and the honey was sold and loaded on the cars, the money collected for it, and all of this was done at an expense of only one-tenth of one percent to the stockholder. This proved very satisfactory to the members. It was also satisfactory to the buyers, as it is better for them to have the honey stored where it can be displayed and they can see it before buying. It saves them time and expense in canvassing the country to buy the honey, and when the honey is stored at the railroad it can be easily loaded at short notice.

The producer is benefited in another way. When a buyer comes here he is at an expense of at least \$10 per day, and that must be paid by the bee-keepers.

Our difficulties have not been with competitors or in finding market for honey, but to inspire faith in the doubting bee-keeper. Instead of its being hard to find a market for the honey, it has been hard to get the honey to fill the demand created. But the two years' business has given us confidence. I don't know of a single member who has given his patronage, that would wish to sell outside another year. Of course we must take into consideration that last year was very favorable for us. Honey was scarce in most sections, and we may have years when it will take the whole ten percent commission to run the business. But should we have an unfavorable year, there are still great advantages in associated work. Buyers, when honey is cheap and plenty East, will not come here as they did last year. But if we are organized we can take our honey East and lay it down in the market at whatever price the producer is receiving. We are on an equality with him, and the rare excellence of our honey is in our favor.

I have now given you a brief history of the workings of the Colorado Honey-Producers' Association. I wish now to point out the possibilities of co-operation, and the obstacles in the way. As to the possibilities, I believe we can find a market through the Association for all honey except that which is required to fill our local demands. Each bee-keeper should try to encourage home consumption, and sell as much in this way as he can, at the same time holding up the market. After that is done, he can market his remaining crop through the Association cheaper than he can do it himself. This has been my experience. In past years it took a good deal of time to deliver in small lots to my customers, and very often I had to stop in the midst of urgent business to deliver a single case of honey. Trade is exacting and must be attended to. Now I deliver to the Association, have no more bother, and receive a better price. This can be true of every bee-keeper in the State. To illustrate this I wish to give you an example: Lately, a bee-keeper in a remote place, wrote us that he had a large amount of comb honey. He had sent agents to Denver several times, and they could not place the honey. He finally put it in our hands. By the time the honey reached Denver, it was sold in the East at good figures, and the draft was on deposit at the bank in Denver to pay for it. This I consider quick work.

I wish now to point out some of the difficulties: It costs money to do this work. To go into the office you will see on file hundreds of letters that have been promptly answered, telegrams and long-distance telephone messages that have been expensive. We issue, also, a crop report. We receive bulletins, posting us on the crop of honey from Colorado, Utah and Arizona. This report is paid for. Money, money, is what it takes to carry on business. We

seem to have some members who do not understand this, and more that are not members that don't understand it. They come to us like this: "What are the prospects for honey this year, and what is the condition of the market?" I have a crop of honey to sell. I wish to co-operate with you. I wish to sell my honey myself. I don't wish to undersell you. What price shall I hold at?" All this information he comes for has cost the Association hard money. But wherein does he co-operate when he does not offer a cent for this valuable information?

The question that is to come before you is, "How can we organize throughout the State and make an equal and just distribution of expense to all concerned?" To make co-operation a success, all must co-operate, otherwise there is friction. To have a successful, intelligent and just co-operation throughout the State, there should be a certain office with a manager in charge who will find out, first, the supply of honey throughout the country, so as to know the condition of the market. He should then be posted on the amount of honey we have in our Association. He is then in shape to negotiate in different parts of the East so as to sell at the best possible advantage.

Now that we have the central office working, we will proceed to organize local associations, which are to be a part of the main association. This local association shall have an office the same as the main one; shall also have a management to correspond with the main office. He shall receive all the honey and see that it is properly graded and classified. He should ascertain how much each member has, and report the same to the general office as soon as possible. The manager of the local point should rent a place for storage and should send a printed notice to each member, saying on what day or days of the week he will receive the honey. Then on the designated days (say Friday and Saturday) he can be there and take the honey. One day in the week will make the expense light, and in small towns storage can be rented quite cheaply.

When the honey is ready he should see to loading the car and billing it out. All this to be done under instructions from the general manager. This expense of rent, salary, insurance and of loading should be paid from the general office.

The freight from all points in Eastern Colorado is the same, hence all will pay to the central office the same percent for selling the honey. That is, the general office pays all expense for storage, salary, etc., and the producers in all parts of the State pay the same for handling. To be sure to have all expense paid, we will say we make the commission ten percent. Then at the annual meeting in January, we have the business summed up and a rebate declared to each member, proportioned according to commission he has paid. This will be absolute justice to each member, and if our local association has only a part of a car it can be loaded and shipped to the association in the next town. In such a case, there is a charge of five dollars for switching the cars; this to be paid by the local association that has only part of a car, and in case each town has only a part of a car this expense should be borne equally by them.

Co-operation carried on in this way will enable the general manager to do all the corresponding with parties East, and perhaps sending a few telegrams. Unless there is harmony among the local associations, such as I have described, there must be friction, the same as we had when selling as individuals. Buyers will take advantage of this and we lose the good that should come through co-operation.

So far, I have not touched on the supply business. This can be managed the same as the honey. If local points wish part of a car, they can have the car so loaded at the factory, that part can be discharged at one station and part at another, and pay a little extra to have the car moved to the next point, and parties at this point should pay the extra charge. I would also suggest that the local managers be directors and should meet in conjunction with the board of directors, elected by the Association. The membership fee of the local association should be the same—ten dollars. This should go to the State Honey-Producers' Association. Each division should be known by letter, as, for an illustration, Longmont, Division A; the next locality that organizes, Division B. Such an organization throughout Colorado will enable us to do business in a very intelligent way. The expense for negotiating the sales of the whole crop done through one head, will be but very little more than for a part of the crop. The price can be maintained because we are not selling against each other. The larger we can make our Association, the more widely will our influence be felt throughout the country.

We soon would be a concern that would be known by every buyer throughout the land. We would be a powerful factor in selling honey in our own State, as we would have strength enough to push our products into the most remote parts of it. We would classify our honey and have a brand, which, when established, would be always called for, as people would know exactly what to order, and would know that the honey would be the same each time.

I hope that we may have an organization that will be patronized by all. It is surely true that an organization of this kind will benefit every bee-keeper that produces a pound of honey to sell, whether he supports the organization or not.

No. 7.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

(Continued from page 408.)

MR. BOND drove into our yard the next morning while we were yet at the breakfast table, and proceeded to unhitch his team without waiting for an invitation. Hastily excusing myself to my family, I went out and found him tying his horses at the watering-trough, about 50 feet distant from his wagon. As he came to meet me he began the following explanation:

"I'm on hand earlier than you expected, you see. Well, when I got home last night and explained things about my all-day's absence my wife laughed and told me that she and Harry had done some bee-business, too. 'The little fellow,' she said, 'while playing in the grove, found a large swarm of bees hanging to a limb of a small tree; and we lived it.' Well, when I went to look at it the idea came into my head like a flash, that the best thing for me to do with that swarm would be to bring it along with me this morning and get you to put it into one of your hives for me. Then I could take it back home with me in the evening. There it is," he concluded, pointing to the wagon. "I tied it up in a sheet to keep the bees in the hive. But some of them got out in spite of my precaution."

"I expected they would attack me and the horses, but they didn't; they just flew around about the hive, and somehow managed to keep up with the wagon till I got here. But, you see, more and more kept coming out. That's the reason why I was in such a hurry to get the horses unhitched."

"That's a new idea of yours, Mr. Bond," I replied. "But I'm thinking that the scheme will not work out as you have planned, because I have an idea of my own about it: I'll furnish the hive and tell you what to do, but I shall expect you to do the work of transferring the bees. First, however, it will be proper to put your horses in the stable, for the job will have to be done right here; or near by, at any rate."

"You see, Mr. Bond," I continued, seeing by a look in his face that he did not approve of my plan. "If we carry that bundle of yours over to the apiary and you do the transferring there, all these bees here that are flying around where they know the hive to be, will be lost to the swarm, because we can't make them follow us. That loss you can't afford, for, as you see, there are now several thousand outside, and more coming out all the time. There is no help for it, that I see, and no time to be thrown away in discussing the matter; therefore, while I go and get a hive, and my smoker, and a bee-veil for you, you hurry those horses into the stable. I'll be back inside of five minutes."

Well, to tell the story as briefly as possible, inside of 30 minutes Mr. Bond's bees were contentedly humming within and near one of my 10-frame hives. Quite naturally he regarded those flying bees as very dangerous enemies until I explained to him that bees thus situated never, or seldom, attack any one.

After carefully adjusting his bee-veil I assisted Mr. Bond in lifting his unique bundle out of the wagon, and together we carried it to a shady corner of the barn-yard, where I had placed my hive. Setting it down he—following my instructions—untied the corners of the sheet and laid the ends out flat, one end toward the new hive and as close as possible up to the bee-entrance. Then he tipped the box over and carefully laid it on its side, with the open end, or bottom, toward and near to the bee-entrance of the new hive. In the top-end of the box-hive had been bored two one-inch holes for bee-escapes, which were plugged. Withdrawing these plugs Mr. Bond began blowing smoke

into the hive, thus driving the bees out and toward the receiving-hive.

One thing, however, I did to assist Mr. Bond: With a small copper scoop, such as grocers use in handling teas, which I had brought from the house with me, I transferred a lot of bees from the body of the box-hive to the new hive, putting two scoop-fuls in among the frames. This established bee-connection between the two hives; and the bees were not slow in seeing it.

Let it be understood, however, that I did not forget to direct my pupil's attention to the fact that there was only one right way to use that scoop without irritating the bees and killing many of them.

"It wouldn't do at all to scoop up bees as you would potatoes," I explained to Mr. Bond. "It has to be done in such a gentle, careful, and yet quick way, that the bees will not find out they are being scooped."

"Now, Mr. Bond," I said, after most of the bees had been driven out of his hive, "there are quite a lot of bees inside that box of yours yet, and the best way to get them out and into the new hive is to tip your box bottom-side up. They will soon all be on the wing, unless the queen is yet with them—that, however, is not probable. In a few minutes you will see that these, and the bees flying about where the wagon stands, will have united, and gradually all of them will go in where the queen is with the swarm."

"This evening you can take them home with you safely and in good shape; but not done up in a sheet, Mr. Bond. I'll show you a better way."

"What do you do that for?" asked Mr. Bond, when he saw me set a piece of board slantingly against the front of the new hive.

"I do that," I replied, "in order that the bees that fly out will mark the location of the hive before leaving it. It is not necessary to do this when a swarm is first hived. But when a hive of bees is moved from one location to another, or a colony is transferred from one hive to another and the location changed, it is always best to take this precaution; because without it many of the worker-bees will never find their way back to the hive after leaving it from a location they have never marked."

"Well, Mr. Bond, you have had a very important practical lesson in bee-keeping this morning; and without getting any stings, I believe. We are now ready for something else. I want you to learn about drones to-day. I presume you remember what I said yesterday about looking after drone-brood in the parent hive of that swarm we hived. Well, that's where you will get your next lesson."

"Here you see the lesson that's before you now," I said to Mr. Bond, pointing to the super on the brood-frames of the old hive, after I had removed the cover."

"That super has to be removed before we can properly proceed with our drone-lesson. That is plainly apparent to both of us. Well, here you have a first-class chance to learn one of the important lessons in bee-keeping. It is something that can't be avoided without detriment either by the great or small bee-keeper. If you should conclude to keep only one colony of bees you must, if you want surplus honey, learn how to put on and take off supers. This interesting and important lesson is now before you."

"All right, I'm ready!" exclaimed Mr. Bond, enthusiastically. "What shall I do first? Smoke into the hive to make them fill up?"

"No," I replied, "the bees in this hive are nearly all baby-bees and don't require heroic treatment. The first thing is, to pry the frames loose from the super with this chisel. If the bees then make a rush toward you, don't dodge, but give them a little smoke. They are rather timid, and easily subdued."

"Then you lift the super off and set it down on top of the cover there"—pointing to the cover I had just removed from the hive—"but in setting it down please be careful that none of the bees on the under side are crushed. That can be avoided by setting the super down rather slowly, and very carefully, thus giving the little things time to get out of the way."

"Be careful now, Mr. Bond!" I cautioned, when he bent down to lift the super. "Make sure that you get a good hold at each end before you lift; because if your hold slips you would quite likely have another fracas with my bees, worse than the first."

"I thought you said, just a minute ago, that baby-bees wouldn't sting," remarked Mr. Bond, looking up, his eyes twinkling mischievously.

"I beg your pardon, Mr. Bond; but I did not say that, exactly. Such an event as your dropping that super was not then thought of. I think there are lots of bees in that

super, and in the hive, too, that are old enough to sting if you hurt them and smash their treasures."

"Besides that, Mr. Bond, I wish to impress this upon your mind to serve you in the future as a bee-keeper: Bees rank very high in the insect world in the degree of intelligence they possess. I have always been guided by that idea—which to me is a fact—in any manner of handling my bees. I believe that bees—young bees—can be spoiled for life by ill-treatment; about as babies are generally spoiled by the wrong kind of treatment, beginning almost as soon as they are born. Now, right here we have a good illustration, which I shall use in order to fix the principle of the matter upon your mind."

(To be continued.)

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editor.)

Swarming-Time Troubles.

What is the matter with me or my bees? I have had eleven swarms and have but two left. They all settled one, except one, and were easy to hive. Some would come out again the same day, and others the next day. Some I put in the third time and then they went away. I clipped the wings of one queen, and still they went away and left her.

My hives are of my own make—Langstroth size, made of white pine with white poplar frames, and foundation starters. ILLINOIS.

ANSWER.—I don't know what is the trouble, but can make a pretty safe guess. The great probability is that your bees would not stay in the hive because it was too hot for them. A cool, shady place for the swarm will help matters. Even in a dense shade it may be so close, with so little chance for a breeze, that I have known combs to melt down in a hive where the sun never shone. On a very hot day, after a swarm is hived, it helps to cool them off to sprinkle well the hive with water. Perhaps more than anything else it is important to see that there is abundant ventilation in the hive. Raise the hive on blocks half an inch to an inch, and at least for a day or two leave the cover partly open, so the air can pass readily through the hive from bottom to top. If the hive must be out in the sun, provide shade for it in some way. Boards laid across the top, weighted down with a stone will do in place of a regular shade-board. An armful of long grass laid on top, held down by two or three sticks of firewood, will answer a good purpose. Some give a frame of brood to a swarm. They are not so likely to desert brood.

I can hardly think the bees absconded without that clipped queen, or some other queen. They may have gone back to their old hive; they may have gone into another hive; or they may have gone off with a young queen which joined them.

A Half-Dozen Questions.

1. How do you separate the honey from the comb in old combs, without an extractor?

2. What is a Van Deusen wax-tube? What is it like, and how used?

3. How do you fasten foundation in shallow extracting frames, 5x18 inches with a groove in the middle of the top-bar, and how do you use wax and rosin in fastening foundation?

4. There was an article in the American Bee Journal of June 6, by F. Greiner, on the management of out-aparies, where he furnishes them a new hive with six Langstroth frames, with starters. (The supers, he says, should be put over an excluder, which, however, may be taken off after a week's time.) What is the super for? I suppose it has been on the hive and he is putting it back.

5. I have some Langstroth frames with thick top-bars,

and grooved for wedges. When the wedges are taken out, doesn't the partition come out and make the frames of no account? It looked that way to me.

6. How about the beveled top-bar?

TENNESSEE.

ANSWERS.—1. I don't know of any satisfactory way except to let the bees empty out the honey. Of course you can melt the whole business, but you will not get a nice article of honey.

2. One of the bee-supply catalogs, says of the Van Deusen wax-tube: This is a very convenient tool for fastening foundation by the melted-wax plan. It is a tin tube for holding and running out melted wax.

3. Slip the edge of the foundation into the groove, then run melted wax along, or drop a few drops at intervals. Another way is to crowd a string down into the groove beside the foundation. You can use wax and rosin half and half, but it is much better to use pure wax. Years ago I used wax and rosin, and then when I wanted to melt up an old comb I had to throw away the upper part, for I didn't want wax mixed with rosin.

4. The super is for the bees to store surplus in. The excluder is to keep the queen from going up into the super. After the brood-nest is established in the lower story the excluder can be taken away, but of course the supers remain.

5. I don't see why the partition should come out when the wedge is taken out, and I don't see that it would matter much if it did. What do you want to take the wedge out for? When it is put in once it ought to be built in by the bees and last a lifetime. If the time should ever come that you would want to replace the comb with foundation, I think you would want a new frame, too. I have had combs that have outlasted the frames, and I have put old combs into new frames, but I don't remember ever putting foundation into old frames.

6. I think they are not liked as well as formerly. For my own use I much prefer no bevel.

Newly-Hived Swarms Deserting.

I have had two large swarms. Of the first one I put some comb in the frames before I hived it, and a couple of hours afterward they left. On examination I found the comb had broken from its fastenings, and lay in the bottom of the hive. The second I let go a week before disturbing, and then only to straighten the comb, of which there was a large quantity partly filled with brood and honey. Two days afterward they left the hive; after settling I put them into a new hive, and they are apparently contented. On examining the hive they left, I found comb that had broken down—a piece about six inches square. The weather is warm. Do you think it the right thing to work with them in hot weather? The hive they left had a double handful of bees, part of which are working. Would they develop a queen? I have no frame of bees to give them.

INDIANA.

ANSWER. There is very little for doubt that there was no trouble except that the hive was insufferably hot. At all times it is important that a newly hived swarm shall be kept cool and well ventilated, but the remarkably hot spell that occurred at the time you mention made it especially emphatic. Ordinarily a swarm is safe to remain after the queen has begun laying, but in such exceptionally hot weather, resulting in the breaking down of combs the heat may be sufficient to drive the bees out of a hive in which even a good start has been made. The breaking down of that comb did not drive the bees out of the hive, but the heat that made it possible for the comb to break down was what did the business.

Yes, a double handful of bees may rear a queen if they have eggs or larvæ less than three days old, but it is not likely to be a very good queen reared by so small a number of bees. It is likely, however, to be a better queen reared in such scorching weather than one reared by the same number of bees in cooler weather.

As to its being right to work with bees in hot weather, if there is anything to be done with them the hotter the better so far as the bees are concerned. The only thing against the hot weather is the discomfort of the bee-keeper. As I write this the thermometer stands 99 degrees in the shade with a chance that it may be higher later in the day, and I am eager to get out to work at the bees. But that does not say that the bees should be kept as hot as possible in their hives. Raise the hives half an inch to an inch

from the bottom-board by putting a block under each corner. It may be well to raise a hive still higher when a swarm is hived, and the cover may be left partly off for two or three days, so that a draft of air can pass directly through the hive. Sprinkling the hive with cold water will bring temporary relief. In the case of your swarm which left the hive after occupying it a week, the probability is that there would have been no such desertion if the weather had been normal, or if you had raised the hive.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

MR. DONALDSON'S SWARM-CATCHERS.

Nice-looking swarm-catchers for a nice-looking apiary, and a nice report Mr. Donaldson makes of their success. Pages 305, 312. Other swarm-catchers of the same patent have been known to fail, however. Get to play—and then no sound less than thunder, and no sight less flamboyant than a regiment of soldiers marching close by, would be altogether sure of attention.

WATER, POLLEN, AND HONEY.

Man's mouth calls for two indispensables—food and drink; and therefore he easily forgets that the bee's mouth calls for three indispensables—water, honey and pollen. It appears that when he supplies the two former abundantly, and they can not find the latter in the fields, nuclei swarm out at a terrible rate, and he, perchance, scratches his head and can't imagine what's up. Page 319.

THAT PROPOLIS CHAP.

Aha! That chap offered 25 cents a pound for propolis because he didn't intend to pay anything. Told you so. Put the price high to get many offers; and figured (correctly) that some of them would consent to the bargain of pay on delivery. Page 322.

NATIVE BREEDS NOT ALWAYS BEST.

The maxim that the native breeds of a country are the most fit for that country (as per page 323) is liable to some very heavy discounts. That which is the most fit to run wild is usually not the most fit under man's care. Again, aboriginal fitness is often only the lack of severe competition. Most countries have their native rats; but they all have to yield to the Norway rat when he comes around. Most countries have their corresponding little birds; but they all have to yield to the English sparrow when he comes around. South America has a great many species of honey-storing bees (Meliponae, Trigona, etc.), but they will doubtless yield the ground, to a great extent, to the foreign bee with which we are familiar. The same may apply to breeds as well as to species. Had South America a breed of *Apis mellifera* it might be nearly on a level with the Meliponae and Trigona, and much inferior, even on its own soil, to the foreigner.

COMMENTS ON DR. McLENNAN'S SUGGESTIONS.

I incline to tell the doctor (Dr. McLeann, page 324) that if he mixes a pound of honey with a quart of water it will be likely to get spoiled long before a family will take it up a spoonful at a dose. Say one-fourth of the quantities.

Canton flannel to hold honey on the skin for medicinal objects, eh? Thanks. But when honey is used for stings it will hardly do to have it in the nap of flannel, as the main object then is to keep the pores of the skin from letting in air.

MR. DOOLITTLE AND OUR COUNTRY.

Aunt Mr. Doolittle's lost \$1,000,000,000. I'm glad the old motto has been amended. It used to be, "Figures can not lie." Now it reads, "Figures seldom do anything else but lie." Not quite sure we need the amendment *this time*. Thousands go pleasureing in Europe with full pockets and come home with empty pockets. Millions of cash have been sent here for investment, won large profits, and then went home profits and all. Many millions every year are sent abroad as interest on all sorts of bonds and things—and that's the last of those millions. Once in awhile a rich American (Waldorf Astor fashion) expatriates himself, millions and all,

Often still, a rich American sends millions to a worthless foreign count—and throws in a daughter. (Last item small loss to the continent.) If we added all this together without any rebates we should get quite a total, sure enough. Glad we have a country big enough to stand it all—stand it all as ox in pasture stands the loss of blood the flies take—stand it all and yet make actual progress in changing from a debtor nation to a creditor nation. And when the aforesaid change is complete some of the above booties will be on other footies. Page 326.

THE LOSS ON SECOND-HAND CANS.

Perhaps you've heard the prosy preacher (who has an hour to fill and not the matter to fill it) say—"a-a-and"—with pauses and emphasis. It seems Mr. Whitney lost a few dimes on some second-hand cans he bought, "a-a-and" a ten dollars on the honey he ventured to put inside. "And" is sometimes a major instead of a minor among the parts of speech. Page 306.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

THE KALAMAZOO OF CALIFORNIA.

I have spent Sunday in the Kalamazoo of Southern California. Some one will say Pasadena, but it is not. It is even more to my mind than is lovely Pasadena. It is none other than

BEAUTIFUL REDLANDS.

As we look up from San Bernardino to the East the Sierra Madre Mountains form a U, and the incomparable city of Redlands nestles right in the bend of the arch. San Bernardino Mountain, "Old Gray Back," the highest mountain of Southern California, ever stands close by, and ever looks down in kindly mien upon beautiful Redlands. The Smiley brothers—Alfred H. and Albert K.—visited this place years ago, and sighted a thin, barren hill reaching high up on the southwest of the town, and overlooking a deep pass to the south, through which the Southern Pacific Railroad trends as it stretches eastward between the two great peaks, San Bernardino and San Jacinto.

These great-hearted and far-seeing brothers, whom to know is to love, at once saw the possibilities of what are now famous as "Smiley Heights." They purchased the barren hill site, carried thither brains, taste, water, cultivation, and all kinds of beautiful plants, and to-day those old, barren hill-sides are transformed into marvels of beauty. To stand on "Smiley Heights," and to look down upon the beautiful homes often almost hidden amidst the most beautiful and thriving orange orchards known to the world, is to view a scene of incomparable beauty.

I hardly need to say that all Redlanders take pains in adorning street, home grounds, and homes. All this touches the refinement and sweetens the life and heart. I have been privileged to look in upon those homes, and share their hospitality. Theirs are such homes, and theirs such home-circles, as taste and beauty must ever fashion. Oh, that there were more Smileys to set the pace, and more laymen to follow in their wake, that we might have more of beauty and loveliness about our homes; that we might have more of cheer and loveliness in our hearts. Few of us have the wealth to fashion such grand parks as are seen on "Smiley Heights," but all of us can help to make a lovely home, and can thus do our little part to make a more beautiful world, and more lovely people.

As I write I look out from my window over the city. I can only see parts of houses, for trees are everywhere. Indeed, all Redlands is a magnificent park, set down in which are cottages, or palaces, as the pocket-books of the owners permit, but all are chaste and beautiful.

Why are there not more Redlands in the way of wooded street-sides and home surroundings? Only because we do not arouse to the fact that such beauty gives richest pleasure, and, better still, touches the heart only to refine and sweeten.

There is another side to this picture. Redlands is perhaps the most thrifty city in Southern California. Of course, that must follow as light the sun. Men everywhere are touched by master-pieces of beauty. They look upon them to admire, to long for, to possess. The uncanny features of wealth are softened, subdued, often erased altogether by a

love of beauty. Thus our Redlands, while they capture the wealth, secure the best and only true aristocracy of wealth. And thus the wealth is turned into the best channels, and we find a society not only cultured in mind but in heart. It has been my happy privilege to address the people of nearly every part of Southern California, and, as we should expect and know, I find no folk anywhere more delightfully responsive and eager to know than are those of beautiful Redlands.

THE GARDEN.

I wonder if all our home circles appreciate as they should the wealth of satisfaction that comes from a well-kept and productive garden. I have thought of this over and over, as I have picked of late, morning after morning, the luscious blackberries and the great, meaty Logan berries. I have wondered where they all come from. Only a few bushes, and get all we want, and some for the neighbors. How little work and how much fun. I wish all the home circles could hear my merry whistle as I pluck those great handfuls of delicious berries. I am sure they would all wish to whistle in like environs. True, the pricklers are there, but the smart is dulled at thought of luscious pies at noon-time, and delicious jam at the tea-table.

I love the blackberry garden. It warms up my whistle in the early morning; it gives me just at the wake-up of the day a chance to be useful, and all for the loved ones who may-haps are yet all unconscious in sleep; it rejoices me that it will relieve the burden of the dear housewife as she marvels how she can add to the savory dishes or break the monotony of the tea-table, or help out at the dinner hour. If I had small boys—my boy has now his own berry garden—how good to let them hoe, and water, and pick, and receive from papa the very top figure for the very finest berries ever grown!

AND PEAS, ALSO.

I said berries, but I did so only because they seem a little more "tony." I think my whistle is quite as merry among the great rows of prolific peas. It is so difficult to get peas right from the market. It was old Isaac Walton, the man who loved to fish, who said, "Doubtless God might have made a better fruit than the strawberry, but doubtless God never did." "Change fruit to vegetables, and strawberries to peas, and I will give a good, warm amen to the sentiment. There is something pretty satisfactory in a right good mouth-water. Well, I just have that all the minutes I am picking the peas. It just seems to hang on the whole forenoon in a kind of unconscious anticipatory getting ready for the most savory dish of peas, that graces most the dinner-table.

ASPARAGUS.

I sometimes wonder if the peas are jealous as they see me look longingly over to the asparagus plants, or hear me whistle jubilantly as I cut the great fleshy stems, that seem to rival Jonah's gourd as they stretch up in a night. I commiserate the home that has not its asparagus garden.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song-words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

To Our Shippers.

About May 1st last, we removed our business from the buildings 120-122 W. Broadway to larger and more commodious quarters at Nos. 265-267 Greenwich St., and 82, 84, 86 Murray St., and we duly sent to our friends in the trade a notice of our removal. Shortly after we vacated the premises (120-122 W. Broadway,) one Joseph M. McCaul, rented a portion of our old quarters, and hung out a sign, "Hildreth, McCaul Co., Jos. M. McCaul, Prop.," with other large signs to the effect that his business is "headquarters for honey, beeswax, maple sugar and maple syrup."

The mercantile agencies report that Jos. M. McCaul is the sole proprietor of the new business, and that he claims to have paid to one Henry P. Hildreth (who has no connection with our business,) a consideration for the use of his name.

We will not comment upon the act of leasing our old quarters and exposing thereon the sign, "Hildreth, McCaul Co.," further than to state that we have instructed our attorneys to apply for an injunction restraining the said McCaul from using the name of "Hildreth" in connection with his business in any manner whatsoever.

We value highly the good name and business we have established by many years of satisfactory dealing with our friends in the trade, and we therefore send this notice so that you may not possibly confound us in any manner with the so-called "Hildreth, McCaul Co."

Our firm name remains as heretofore, and all our business is carried on at our new quarters—

Nos. 265-267 Greenwich Street,
and Nos. 82, 84, 86 Murray St., New York, N. Y.

Respectfully yours,

HILDRETH & SEGELKEN.

DO YOU WANT A HIGH GRADE OF Italian Bees and Queens?

2-frame Nucleus with Untested Queen, \$2.00, purchaser paying express charges.

Naperville, Ill., May 28, 1901.
DEAR SIR:—Bees arrived in good condition. Transferred them to hive and gave them honey. Have reinforced them with Italian brood. Are working when not too cold. Have right color, and are satisfactory. D. B. GIVLER.

I like your way of packing bees to express.

GENERAL ITEMS

Prospects for a Large Honey-Flow.

The prospect is good for a large basswood flow, which will be out in about a week. Alsike and white clover are yielding well now. I. A. TRAVIS.

Wood Co., Wis., June 29.

Bees Doing Fairly Well.

Bees are doing fairly well here. I wintered 6 colonies, and have increased to 12. I have prevented all swarming, though they are very strong in bees. They have already stored six supers of honey.

I have three kinds of bees, and the leather-colored Italians are the best. JAS. H. KNOTT.

Preston Co., W. Va., June 22.

April Weather Hard on Bees.

I put 42 colonies of bees into winter quarters, and 40 of them came through safely, but one died in April of spring dwindling. April was a very hard month on bees, only 13 days out of the first 23 being sunny. On April 6 last year I moved my 29 colonies of bees from Tyngsboro to this place, and there were not two days in succession that the bees did not go out foraging. This year there were five days in succession that no bees were flying. JOHN T. COBURN.

Middlesex Co., Mass., June 22.

White Clover Dried Up.

White clover is about dried up, three weeks ahead of its usual time. Basswood is just beginning. I can't tell what it will yield yet, but it looks well. E. M. JONES.

Dane Co., Wis., July 1.

Finds Bee-Keeping a Pleasure.

I was born in Hillsdale Co., Mich., April 16, 1893, and lived on a farm until about 18 years of age, when I began attending high school in Hillsdale. From that time until 1897 I was in school work, either as student or teacher. In the fall of 1896 I married Miss Mazie E. Harmon, of Mason County.

Because of the confinement of school work, my health began to give way, and we decided to locate on a fruit-farm. So here we are in the midst of the Michigan fruit-belt, with more than 2000 trees to look after. We have daily mail delivery, telephone connections, and are pleasantly located to enjoy life.

During the fall of 1898, while making a small business transaction with one of my neighbors, he proposed to turn three colonies of bees over to me in the deal. I knew nothing about bees, that is, so far as management was concerned, but I have a honey-tooth, and am somewhat curious to learn the habits of plants, insects, etc., so the deal was made. The neighbor agreed to deliver the bees and pack them for winter, and he did as he agreed, but he packed them too tight.

Of course, as soon as I purchased some bees I began subjecting everything I could find on bee-raising, getting ready to manage them the next spring. Spring came, and one fine day my neighbor came over to unpack the bees and get me started. As I said before, he had packed them too tight, and all were smothered. The honey was there, but the bees were dead. My neighbor was perplexed and disappointed, and of course I was. But he left me the honey, and gave me another colony in a very poor box-hive, and I began to work with my bees.

During June they swarmed, and I hived the new swarm on the old stand, and soon transferred the old colony to a movable-frame hive. I did not get much surplus last season, but to make another good colony in the fall, and

To make cows pay, use Sharps Cream Separators. Book "Business Dairymen" & Co., 212 free. W. Chester, Pa.

The Queen Establishment

—OF—
O. P. Hyde & Son, Hutto, Texas,
IS FOR SALE.

This establishment consists of 5 entire apiaries, 500 nuclei, and everything connected with the business. Hyde's superior long-tongued stock of straight Golden and light home bred 3-banders, have no superiors. Full particulars, prices, cause for selling, etc., made known on application. If interested, write at once.

Farm Wagon Economy.

The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., who make this Electric Handy Wagon and the now famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

ELECTRIC

This wagon is composed of the best material throughout—white hickory axles, steel wheels, steel bands, etc. Guaranteed to carry 400 lbs. These Electric Steel Wheels are made to fit any wagon, and make practically a new wagon out of the old one. They can be had in any height desired and any width of tire up to 8 inches. With an extra set of these wheels a farmer can interchange them with his regular wheels and have a high or low-down wagon at will.

Write for catalog of the "Electric Line" to Electric Wheel Co., Box B, Quincy, Ill.

packed them all on the summer stands for winter. Two of them came through the winter in good condition, and the other one not so good. Two have swarmed, and all are working well on clover now.

I consider that the knowledge gained and the pleasure derived from the bees pay well for the venture, and I expect to eat some fine honey this year, and continue to study the habits of the little bee. H. D. STOWELL.
Mason Co., Mich., June 24.

Some Kinks in Bee-Keeping.

Tack a piece of fine wire-cloth over the valve on the smoker bellows. This will keep other people from spoiling the spring by sticking their fingers through, as well as to serve to keep bees, etc., from getting in and preventing the valve from closing.

In wiring frames start the tack slanting. Then fasten the first end of the wire to the bottom, and the last one to the top. Driving the tack draws the wire tight. The "A. B. C." book says, "Do not have it tight," but an experience with over 10,000 frames this season shows that the tighter the wire the more good it does.

Two horizontal wires seem to be enough even with 10 sheets to the pound, except for swarms. Then the weight of the many bees will make almost anything sag on a hot day.

Put the spacing staples on the bottom end of the end-bar instead of the top. By so doing one will avoid smashing bees when lifting the frames out in a hurry. This is the method used by the Cogzshalls and other rapid workers. These staples should be used on all frames, whether shut top-bar or not. They also keep the end-bars from getting stuck fast at the bottom.

Wear a pair of bicycle pants-guards when at work in the apiary, and thus keep the bees from getting inside of your trousers.

Always give the visiting small boy (and the big ones, too) some honey. When they know that they can get it by going when the owner is there, they will not visit his apiary for it when he is absent. HARRY HOWE.

An Old Time Honey-Flow in Ohio.

The past spring here was a very poor one, and we had to restock some of our nuclei the second time.

We are having an old-time honey-flow for the first time in three years, and we appreciate it very much. The prospect for its continuance is good. H. G. QUINN.

Eric Co., Ohio, June 26.

Bees, Bears and Turtles in the Mangrove Swamps.

Bees are in fair condition, but the honey season is very late here, and but little honey has been stored yet.

I have moved two apiaries to the mangrove swamps, where we elevated the stands about seven feet above ground, so as to be sure to have them above water in case of a sale. I am now fixing to move the mangrove swamp, where there are about 100 acres of solid mangrove trees within a mile of the bees. You can imagine what a job it is to build stands seven feet above the ground for 100 colonies, and have room to work with them. Also to build a barbed-wire fence around them that is bear tight and bull strong.

Bears are quite plentiful here. W. A. Martin and F. L. Prang heard queer noises across the creek from Mr. Prang's home the other day, and upon investigating found two bears and two cubs. They shot the bears, and took the cubs, that would weigh about 25 pounds each. Mr. Martin took the cubs to Ft. Pierce, where he sold them for \$10. He

was on the ocean beach hunting turtle-eggs yesterday, and found a place that was badly mixed up with bear and turtle tracks, which showed a severe struggle had taken place. Following a trail leading back in the bushes for half a mile he found a 200-pound turtle partly eaten. He dressed the turtle and took the meat home, bringing me a generous mess of it. These turtles come out on the ocean beach at this time of the year to lay their eggs, which are about as large as hen's eggs, but not so good. They lay from 100 to 200, and then go back into the ocean again. The turtles sometimes weigh 1000 pounds, but I never saw one that weighed more than 400 or 500 pounds.

I was shot on Feb. 16, and have hardly gotten my usual strength back again. I was intending to commence extracting to-day, but it has rained hard all day. H. T. GIFFORD.

Brevard Co., Fla., June 11.

Amount of Honey Stored in a Day.

My bees came through the winter in rather poor condition, but they are doing well at present. I have two colonies of pure Italians that occupy three 8-frame brood-chambers.

I have been away to school, and did not get home in time to give my bees the attention they should have had. I have been surprised to find how ignorant and afraid most people are of bees when they come in contact with them, but how much they know about them if they never have had anything to do with them.

My father became anxious to know how much honey the bees stored in one day, so he made what he calls a pair of "scales." He measured off one-half of a plank and rested the middle on the edge of a board. On one end he fastened a colony of bees that had been hived only a short time before, and on the other end a rock that would just balance the weight of the hive and bees at dusk. He put on bricks as the hive grew heavier, claiming that as he weighed the bricks he could tell just how much honey was gathered in a day. One evening the scales showed about 8½ pounds gain, but it was 4 pounds lighter in the morning. LESLIE HAZEN.

Nemaha Co., Kans., June 19.

Supersede and Control of Queens.

Dr. C. C. Miller says in the American Bee-Keeper:

It is undoubtedly cheaper to let the bees themselves do the superseding than to replace queens with others, either purchased or purchased; but the wise bee-keeper will still keep the whole matter under his control by suppressing all poor stock and encouraging the good. From time to time he will seek to improve by introducing fresh stock from the best queen-breeders; but he will not stop at that. He will keep tab on the performance of every colony, and be able to tell you just what the progeny of each of the queens did during the preceding year, or years, of their lives; and knowing this, he will know from which queen he is to rear. This matter of keeping a careful record of the performance of each colony is at the foundation of building up an apiary that is to bring in the best returns. How many bee-keepers do you suppose keep any such record?

If you have never given the matter any attention, perhaps it may be well to recall some facts that you have probably noticed without carefully considering their bearing. You may have noticed that, as a rule, the colonies most given to swarming have not been among the best for storing surplus, and that those which have made the best super records have not wasted much time in swarming. If you have paid no attention to this, but have left the bees to run things their own way, the bees most given to swarming are the ones that have given you increase almost entirely.

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

while your best colonies have given no increase. Don't you see that such a course, continued indefinitely, will inevitably result in run-out bees? By keeping matters under your own control, you can make the current run the other way.

Introducing Queens With Tobacco-Smoke.

Here are instructions that I am sending out this year for introducing queens, and guaranteeing the safe introduction. After giving notice of the date when the queen will be sent, I say:

As soon as you receive this notice, remove the queen from the colony to which you expect to introduce the new queen. When she arrives, put her away in a safe place until after sundown, just at dusk, then light your smoker, and when it is well to going put in a pipeful of smoking-tobacco, put on the cover, puff until you get an odor of tobacco, then puff one or two good puffs into the entrance of the hive. Wait two or three minutes, then send in another good puff, remove the cover, drive the bees down with a puff of smoke, open the cage and allow the queen to run down between the combs, following her with a puff of smoke, and put on the cover. Half an hour later, light up the smoker again, putting in the tobacco as before, and blow two more good puffs in at the entrance. If no honey is coming in, feed the colony a pint of syrup each night from the inside of the hive, but don't disturb the brood-nest for four or five days.—Bee-Keepers' Review.

Weight of Wax-Scales.

E. F. Robinson gives this interesting bit of information in the Canadian Bee Journal:

While making a display of the natural history of the bee a few weeks ago, I took the trouble to sort out a lot of wax-scales from some fine refuse, and arranged these, the natural scales, into the word WAX, but before doing so I weighed a number on a pair of jeweler's diamond scales to find out how many went to the pound, for I could not find any reference to this in any of the many books on the bee. I find there are just 192 to the grain, and of course 1,474,560 to the pound.

Inversion of Brood-Combs.

This has been found profitable by Mr. L. E. Eshenower, of Pennsylvania. In the fall he takes away all combs not covered by the bees, taking good care of them, and in the spring he returns them, *upside down*. He uses an invertible frame of his own make, and slightly opens the openings of the combs when he returns them to the hive. He believes that he has prevented many cases of spring dwindling by this practice. He admits that inversion has been cast off long ago, but, very wisely, says that we sometimes cast away something that we *think* we have tried, whereas, we have scarcely made its acquaintance.—Bee-Keepers' Review.

Co-operation Among Bee-keepers.

The June number of the Rocky Mountain Bee Journal is almost entirely taken up with the matter of co-operation among bee-keepers. Those Coloradans are not merely theorizing on the matter, but have been putting in practice some excellent co-operative work, some what to the advantage of their pockets. It seems that they have so enlarged the work that they now have, under the title of "The Colorado Honey-Producers' Association," an office kept open the year round in Denver, with Frank Rauchfuss as its energetic manager. The following interview with Mr. Rauchfuss is given in the paper mentioned:

"I find advantage, if any, accrues to stockholders in the Colorado Honey-Producers' Association, besides dividends on their

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly ex-

plained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

stock, in the purchase of supplies through that Association?"

"You should emphasize the fact that the Association was formed to enable its members to market their honey profitably. We kept up the price of honey last year very successfully. We handled a large share of the honey crop. Our members got the best prices for their honey; and at the close of the season we were able to return them 35 percent of the usual commission. Handling only honey we could not afford to keep a store open the whole year. By expanding our business we are able to keep the store open all the year; to keep in closer touch with the bee-keepers and the trade, and to handle the business more successfully, because more intelligently. You know that supplies are cheaper than last year. We claim part of the credit for that. The State Association deserves part of the credit, perhaps the larger part. Any one who will compare the price-list of last year and this year can figure out the advantages for himself."

"2. Has the handling of supplies by the Association tended to cheapen the price of supplies in the city of Denver?"

"Compare the lists," said Mr. Rauchfuss. I compared. Eight items from last year's price-list footed up \$9.42; the same eight items from the price-list for this year amount to \$8.24. These are staple articles. The difference amounts to a trifle less than 13 percent of present prices—a saving worth considering."

"3. Would you favor the establishment of branch associations for the handling of supplies, subsidiary to the main association in the smaller cities throughout the State?"

Mr. Rauchfuss answered with an emphatic "Yes!" and then walked away to wait on an impatient customer.

Horehound Honey.

H. H. Hyde says in the Southland Queen that horehound is in his locality in Texas, "and sometimes it ruins a good deal of honey in the fall, but in the spring it fortunately blooms early enough so that all the honey is consumed in brood-rearing."

Fastening Foundation.

C. Davenport fastens foundation in brood-frames or sections by means of something like a large medicine-dropper or pipette. He says in *Gleanings in Bee-Culture*:

Mine is made of a tin tube about 4 inches long, and not quite 1/2 inch in diameter. The lower end of this tube is gradually tapered down to a point, so the hole at the extreme end is a little less in size than what it would be on an ordinary lead-pencil if the lead were removed to the upper part of the tube. A rubber apple or bulb is attached, and it is important to have this rubber fit over the tube tight enough to exclude air. When the lower end is placed in melted wax, or any other liquid, with the rubber bulb compressed between the thumb and finger, as soon as it is allowed to expand by air suction, it draws some of the liquid up into the tube. By allowing the rubber to remain expanded the tube will not leak when withdrawn, no matter what position it is held in. Pressure on the rubber forces the liquid out slow or fast, just as desired.

Does a Queen Carry Foul Brood?

The editor of the Australasian Bee-Keeper says:

My opinion on the matter is so decided that should I need a queen from a foul-broody apiary I would introduce her into a healthy colony of bees without the slightest hesitation or fear of communicating the disease. I would, however, deal very deliberately with any bees accompanying the queen. Every one would be crushed and afterwards burnt. In my opinion, it is the bees only that communicate the disease, and not the queen. To back up my assertion, I may say I know of numerous queens from foul-broody colonies having been introduced to healthy bees, and

have yet to find the queen blamed for communicating the disease. When I got a queen from elsewhere, or an imported queen, I open the cage before a closed window, and after the queen is caged I destroy every bee. Most of them are readily crushed when flying against the window glass.

Extracting Supers Over Winter.

In the Southland Queen, Louis Scholl tells that he practiced putting enamel cloth over his brood-frames and piling the extracting-supers above for winter. He says further:

But this had to be removed in the spring, so last year I tried some of the heavy brown paper used by butchers, and putting a sheet on top of the brood-frames, by just tilting back the supers and all above. If honey is in the top supers, a hole can be torn in the sheet of paper to let the bees go for it above.

I would prefer to have the sheet of paper a little narrower than the hive is wide inside, leaving a passageway next to the walls.

In spring, as soon as the colony gets more populous, and more room is needed, the bees will attend to the paper, gnawing it away, and saving the apiarist the labor of removing it.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This nicely illustrated, contains 100 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Doolittle.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and beekeeping. No apiarian library is complete without this standard work. Rees, L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in beekeeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Honey-Rearing, as Practically Applied, by G. M. Doolittle.—This method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book. 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of beekeeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 100 pages, bound in paper. Price, 25 cents.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cents.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cents.

Foul Brood, by A. R. Kolnik.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others. Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field. Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field. Tells everything about Poultry Business. 64 pages. Price, 20 cents.

1901—Bee-Keepers' Supplies!

We can furnish you with The A. I. Root Co.'s goods at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price paid for beeswax. Send for our 1901 catalog.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 19.—New comb honey has not yet reached this market. It would sell at 150c per lb. if choice white, and the common at 130-135c. The market is entirely bare with exception of a few cases of a lot that we had held for us, expecting it would be needed. Advertisers are that shipments will be started by July 1. Very little trading is being done in extracted, as larger dealers will not contract this season unless at low figures; some sales of amber have been made at 44½c for early autumn delivery; white is held at 54c. Beeswax sells at 30c.

R. A. BURNETT & CO.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from ½ to 1 cent per pound.

C. H. W. WEBER.

BOSTON, June 29.—There is practically no comb honey in our market, and owing to warm weather very little call for it. Are expecting some new comb early next month. Market for extracted dull, at 4½¢ per lb.

BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00. PEYCKE BROS.

NEW YORK, June 1.—Extracted honey is exceedingly dull and very little moving. We quote for the present: White, 66½¢; light amber, 55½¢; amber, 50¢. The demand for comb honey at unchanged prices. New crop is now beginning to arrive from the South, and sells at from 12½-15c, according to quality and style. Beeswax, 27c. HILDETH & SEGELKEN.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts or stocks and little demand. It is between seasons now. Prospect of good crop in this vicinity from what bees there are left, the greater probability. New crop is being killed by foul brood exterminators. H. R. WRIGHT.

DETROIT, June 27.—Very little old honey in market, and no new honey come in yet. Splendid showing for a good yield of white clover honey. Beeswax, 26-27c; demand light.

M. H. HUNT & SON.

BUFFALO, June 26.—Honey not wanted till cool, fall weather. Little old honey here and dragging, 60-65c. Extracted not wanted. Fruit takes place of honey now. BATTERSON & CO.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being granulated. Sales are light at 15 cents for best grade No. 1 Colorado. Amber, 13c. Beeswax firm at 25-30c.

W. R. CROMWELL PRODUCE CO.,
Successors to C. C. Clemons & Co.

SAN FRANCISCO, June 5.—White comb, 11½¢; 12½¢; amber, 90-100¢; dark, 90-100¢. Extracted, white, 50-60¢; light amber, 48-49¢; amber, 36-46¢. Beeswax, 26-27c.

Dealers are very leary in their ideas, but are not securing much honey at the prices they name. In a small way to special trade an advance on quotations is being realized.

Wanted Fancy White Comb Honey in new cases. Extracted Honey. State price, delivered. We pay spot cash. FRED W. MUTH & CO., Front & Walnut Sts., Cincinnati, Ohio. Reference—German National Bank, Cincinnati. 28A17t Please mention the Bee Journal.

BEES WAX We will pay 22c cash, per lb. for pure, bright yellow beeswax, and 20c cash, per lb. for pure, dark beeswax delivered here. CHAS. HARRIS, MEDICINE CO., Des Moines, Iowa. 27A13t Please mention the Bee Journal.

A Bee-Keeper's Paradise.

En route to El Paso.—I have just come from a county about
40 miles square that has more bee-keepers to the square mile than
any other locality of its size I ever visited. The inhabitants talk
bees at the hotels, on the streets, and everywhere, just as farm-
ers talk crops and business in the North. This county produces
more honey than any equal area, I believe, in the United States.
Some say that its yearly output is a *whole trainload of honey*; but
many aver that this is too low, and that two whole trainloads
would come nearer the truth. Of course this great amount doesn't
go all in one lot, but in large and small shipments.

The average per colony is high, and there is a honey crop
every season. It is estimated that in this one county, outside of
the towns, nearly one-half the population are bee-keepers.

The great bulk of the honey is of the very finest, and some of
it is literally water-white. There are thousands and thousands
of acres of honey-plants on cheap land; and bees—there are not
enough to gather it all.

The bees commence swarming early in the spring; and, when
the main honey-flow commences, actually stop swarming, destroy
cells, kill off the drones, and commence business. Did you ever
hear the like of it before? You say, "No, and no one else."
Well, I think I can prove every statement; but for the present I
am not at liberty to give the place or other details; but very
shortly I'll tell the whole story, with some fine pictures.

This is only one of the good things in store for readers of
Gleanings in Bee-Culture. Send 15 cents for three months' trial
or 25 cents for six months' trial, or \$1.00 for one year and one un-
tested Italian Queen. Send \$2.00 and we will send Gleanings one
year and one of our Red Clover Queens. Speak quick if you want
one.

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor

CHICAGO, ILL., JULY 18, 1901.

FORTY-FIRST YEAR
No. 29.

WEEKLY

TELLING THE BEES.

Out of the house where the slumberer lay,
Grandfather came one summer day,
And under the pleasant orchard trees
He spake this wise to the murmuring bees :
 " The clover-bloom that kissed her feet
 And the posy-bed where she used to play
Have honey store, but none so sweet
As ere our little one went away,
O bees, sing soft, and bees, sing low :
For she is gone who loved you so."

A wonder fell on the listening bees,
Under those pleasant orchard trees,
And in their toil that summer day
Even their murmuring seemed to say :
 " Child, O child, the grass is cool,
 And the posies are waking to hear the song
Of the bird that swings by the shaded pool,
 Waiting for one that tarrieth long."
"Twas so they called to the little one then,
As if to call her back again.

O gentle bees, I have come to say
That grandfather fell asleep to-day,
And we know by the smile on grandfather's face
He has found his dear one's 'biding place.
So, bees, sing soft, and bees, sing low,
As over the honey-field you sweep—
To the trees abloom and the flowers ablow,
Sing of grandfather fast asleep ;
And ever beneath these orchard trees
Find cheer and shelter, gentle bees.

—EUGENE FIELD.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

☞ If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one (of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

"MY WIFE came pretty near calling me honey last night."

"So?"

"Yes. She called me beeswax."

DR. C. C. MILLER, of McHenry Co., Ill., wrote us July 10:

"102 degrees in the shade to-day. I don't remember a day so hot before. Neither do I remember so dry a summer before. Much of the grass looks as dead as in winter. A very blue time for bee-keepers."

THE AUSTRALIAN BEE-KEEPERS' REVIEW is the latest candidate for the favor of bee-keepers. Pity that a journal so neatly gotten up could not have had a name all its own, without the danger of its getting mixed up with a very excellent bee-paper published on this side of the globe.

MR. J. T. HAIRSTON, of Cherokee Nation, Ind. Ter., wrote us July 9, as follows:

"We are having the most disastrous drouth and hot weather ever experienced here. Corn and hay are beyond help, bees are doing nothing, so no surplus honey."

"I was waylaid and shot April 12, my thigh being broken, and also badly cut. I am crippled for life. Six weeks later my little girl, Jennie, had her hand crushed in a feed-mill. It had to be amputated."

"I have 175 colonies of bees."

Surely, Mr. Hairston has more than his share of troubles. All our readers will sympathize with him in his many misfortunes.

MR. GEORGE B. WHITCOMB'S home apiary is shown on page 455. It will be observed that he has both the unpainted and the painted hives, preferring the former in that excessively wet climate. The stands used for them are the best kind for there, and he thinks the advice given that person in Multnomah County was poor, when he was told that hives on the ground or near it, and covered with snow, were all right. Mr. W. has seen the snow so full of water there that it would fill the hives and drown the bees. In fact, a neighbor bee-keeper, Mr. Christensen, lost 40 odd colonies just that way. Also an observatory hive containing one comb would not work there, as the nights are too cool at any time of the year.

Mr. Whitcomb had just bought the apiary of Simon A. Nickerson, situated in Linn County, and spent a few days in knocking out the swarming-fever; he believed he had succeeded completely. Mr. Nickerson is one of the old subscribers to the American Bee Journal, and has been counted one of the best bee-keepers in Oregon in his time, but he has been rapidly failing for the past two years, until now his lower limbs are completely paralyzed, and he is bedfast, being able to move only the upper part of his body, with a cord suspended from the ceiling, to which a handle is fastened. This is sad indeed.

Looking over Mr. Nickerson's apiary, Mr. Whitcomb can see the history of bee-keeping

for a number of years past. The majority of his colonies were in modern dovetailed hives of the 8-frame and Johnny-board pattern, but a few were in the old 10-frame chamfered-edge A. I. Root pattern of 15 years ago, of which there are 30 or more neatly piled up along the fence.

The solar wax-extractor is there, and so is the Porter bee-scraper; the Alley queen and drone trap, and numerous other things have been tried, but the best thing Mr. W. has seen for real, downright good service is a pair of frame-tongs. They are like pliers, made just wide enough when open to slip over the top-bar and hold it firmly between two lugs (one in each jaw) that are pressed into the wood when closed; while one of the jaws is longer than the other, so as to be used in prying apart supers, hive-covers, etc. In fact, he thinks it is the best tool for handling cross bees that he ever saw, as with it he can manipulate the frames with one hand while keeping the smoker in the other.

MR. A. I. ROOT is in danger of making trouble for the government. He is not entirely satisfied with its course in the liquor problem, and he thinks the Agricultural Department might issue a bulletin about tobacco just as well as about beans, sugar, eggs, etc., giving its value as an article of steady consumption. He says in gleanings in Bee-Culture:

"I wish I had influence enough with the Agricultural Department at Washington to induce it to publish a bulletin with a heading something like this:

"Tobacco, and its General Effect on the Human Family. Should its Cultivation and Dissemination be Encouraged or Discouraged?"

Then I should like to have a closing chapter something like this:

"The Effect of Tobacco on Children and Young People. Should its Use be Prohibited to these under certain Acts? If so, what Age? Also a Consideration of the Cigarette Habit."

ROBERT W. POLLEY, of Middlesex Co. Mass., writing us June 10, said:

"I have successfully transferred, united, Italianized, and fed up weak colonies all from items taken from the American Bee Journal, besides wintering bees safely; and, in fact, all the good I know about bees I have studied out of that paper. It is needless to add that I am very much pleased with it."

MR. E. E. HASTY, of Lucas Co., Ohio, wrote us July 5, as follows:

"I didn't think, with such bad wintering and bad spring, that such a rush of swarms—the greatest for some years—would ensue. I thought there would be almost no swarming at all. That's the way when we keep bees. The unexpected happens."

Queen-Clipping Device Free....

THE MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping queen wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,

GEORGE W. YORK & COMPANY,
Chicago, Ill.

ESTABLISHED IN 1861 BEE JOURNAL THE OLDEST BEE-PAPER IN AMERICA

41st YEAR.

CHICAGO, ILL., JULY 18, 1901.

No. 29.

✱ Editorial. ✱

The Thousand Members of the National Bee-Keepers' Association (for the balance of about 200) which we are trying to secure among the readers of the American Bee Journal, are coming in slowly. As promised, we begin to publish the list of those that are going to help make up the number necessary to have an even 1000 by the time of the Buffalo convention in September. Since we began this effort, we have received the following names with a dollar each:

W. D. Phillips. H. B. Shoonover.
W. J. Forehand. C. H. Harlan.

We hope by another week to have a much larger list of names of new members to publish.

Are We Doing Our Best in Breeding?—While the theorizers are having their say, and are doing some good by stirring up to a full knowledge of what is required in scientific breeding, are the rank and file of bee-keepers doing their best with what they do know? It is not difficult for any one to understand that if he has a colony that gives twice as much as the average in surplus, and another that gives only half as much, if he makes his increase by swarming, and gets more swarms from the poorest than from the best, that his stock will grow worse instead of better. And yet are there not thousands who will get their increase just by allowing the bees to have control of swarming? And in that case is it not generally the case that the poorest stovers do the most swarming? We can not control the matter of mating to a very great extent, but are pains taken to control it as far as possible? Are drones superseeded in poor colonies and encouraged in the best? If we do the best we can with what we have and with what we know, will we not be doing a good deal better than we are now doing? These are trite words, but it is none the less important to stir up your pure minds by way of remembrance.

Bee-Keeping on Paper.—If a bee-keeper is down with a fit of the blues, one way to cheer him up is to give him a good supply of reading-matter about bees, taking an average lot as found in agricultural and other papers. It is true that some agricultural papers have bee-departments that are reliable, but most of them are more or less re-lie-able. In the Twentieth-century Farmer is an article of some length telling about

"traveling bee-colonies" owned by C. I. Graham, in California. Some of the items may be of interest to the readers of the American Bee Journal, who are left to separate fact from fiction.

The renaissance activity of bees depends upon the coming of spring flowers, and early in the season it is easy to move them before they have aroused themselves from the winter's listlessness. When Mr. Graham moved his bees in April, it was predicted that they would desert him by the wayside, for while bees may be moved in winter, it is generally considered impossible to move them in the active season. The difficulty was solved by traveling at night. He has a wagon the size of a flat-car with crate on it holding 300 colonies. Under cover of darkness the crate is slipped from the car to the wagon, and the bees taken to some sweet hover before daylight. When the combs are full the honey is "strained."

The same paper contains an extract from the New Orleans Times, describing the Cuban bee. It says "he" is quite different from the American bee. The Cuban bee is lazy, trifling, almost slovenly, looking like a drone when compared with the American bee.

"The Cuban bee has a sort of oxcart movement when he goes about his work. The American bee is snappy, quick and almost electrical. Now, why is this? I have my own theory, and I base it upon the broadest principle of science, a principle universally recognized for its potency in the shaping of character. It is a matter of environment."

"The Cuban bee has been surrounded by slow methods and awkward, crude ways of doing things. He simply reflects the life, the mannerisms and the methods about him. He is still the bee of the oxcart age, and buzzes about his business in an oxcart gait. He is a Cuban to the manner born. The American bee's industry may be accounted for in the same way. He is a natural-born hustler. He is an American, full-blooded and full-begged."

What Do We Know About Breeding?—Several writers have had considerable to say as to the ignorance of bee-keepers with regard to anything like the intelligent breeding of bees. It is probably a fact that among the breeders of horses, cattle, swine, poultry, etc., there will not be found so much ignorance as to the laws of breeding as is to be found among breeders of bees. So it is well that of late so much has been said by way of arousing attention to the subject, albeit it may be in the wish of many that more of instruction had been given by those who find fault with the lack of knowledge. To the question: "What do we know about breeding?" the plain answer probably must be, little or nothing.

After all, are bee-keepers so greatly to

blame for this? In intelligence they will probably rank with breeders of other classes, and other things being equal, they should know as much about the laws of breeding. But other things are *not* equal. The breeder of horses may make himself acquainted with the laws of breeding, and in applying those laws for best results one of his chief cares, if not his chiefest care, is to make a wise selection of the two intended parents of his future stock. Without this care in selection his efforts will count for little. In the case of the bee-keeper such selection has been considered next to impossible of accomplishment. Of what avail to study carefully just the drone that should meet a certain queen, if the control of that drone is entirely out of the question? There is excuse for the fact, if it be a fact, which is not here denied, that bee-keepers know less about breeding than the breeders of any other class of stock.

At the same time it would be a gain if more were known as to the laws of breeding. Possibly we are just on the eve of entire control of fertilization, and it would be a wise thing to prepare for it in advance. Even if we have only a very limited control of the mating of queens, it will do no harm to have all the knowledge that can be used in that limited control.

Are Long Tongues of Value Per Se?—In an able article which we copy on page 453, Frederick B. Simpson says:

"To my mind the long-tongue agitation is too much like treating a *symptom* instead of the *disease itself*. I believe that long tongues are of value only in so far as they represent an increase in vigor; or, in other words, only when such increased length is the direct result of increased *use* of the tongue, indicating greater activity and vigor."

That might be understood as meaning that in and of itself there is no value in a long tongue, only as it is a sign of other qualities, just as there is no value in the hands of the Italian only as they are a sign of special qualities possessed by the Italian. It is doubtful that Mr. Simpson meant just this, for elsewhere he says, "Other things being equal, I want long tongues."

Given two bees exactly alike in all other respects, one having a longer tongue than the other, and there is no question that the longer tongue would have the advantage wherever there were flower-tubes a little deeper than the reach of the shorter tongue, and yet within reach of the longer tongue. At the same time it is a mistake to suppose that the length of tongue is an exact gauge of the value of two different bees. The bee with shorter tongue may have extra diligence to make up for shortness of tongue.

Number of Frames in an Extracting Super.

BY C. P. DADANT.

CHAS, DADANT & SON: We take the liberty to ask you for your valued advice and experience in regard to frames to use in extracting supers. The object is, whether or not you consider it advantageous to use less frames in an extracting super than in the brood-chamber below, when the extracting super is of the same width as the brood-chamber which commonly takes 10 frames. Kindly give the number of frames you would recommend as most practical to use in an extracting super of the above-mentioned description. JACOB WAGNER.

The combs containing honey are usually thicker than those used for brood, and for that reason apiarists have universally adopted a wider receptacle for extracting supers than for the brood-chamber. The honey-sections used generally are the 17 inches in width. In an eight-frame hive, six sections are used in the width, leaving a small space for followers. In the ten-frame hive only seven sections are used, and this leaves a still greater space for followers.

In an extracting super the number of shallow frames to be used should be at least one less than in the lower story. For this reason we do not like any super frames which occupy fixed distances. We want to be able to use more or less frames, according to their condition. In an ordinary ten-frame hive, we would not begin with more than nine frames in the super, equally distanced. After the combs are built out by the bees, they are thicker, and the number can be reduced to eight in the space formerly occupied by nine. The bees lengthen out the cells and make a thicker comb out of each. There is less handling, less uncapping, and more honey. We used old style Quinby hives years ago, which contained only eight frames of brood-comb. In some of these hives we successfully harvested extracted honey on six combs. Those combs therefore occupied about two inches each from center to center.

With a hive in which the combs occupy fixed distances, such a spreading of the frames would be inconvenient, and in some styles of hives it would be entirely impossible. So the loose-hanging frame hive, which has sneeringly been called a "rattle-box" by some apiarists, is certainly advantageous in this case.

In our large hives, measuring 16½ inches in width, we use a super slightly narrower—16 inches inside—and this is supplied with 10 frames at the outset. Then the number is often reduced to nine after the combs have been built out. The extra comb is employed to start some new colony in its super. It is a bait.

One has to experience the advantage of wide extracting-combs to realize fully the gain in time and honey secured by this method. It is no more labor to uncup a comb weighing five pounds, than to uncup one of the same surface weighing only three pounds. It is really easier to uncup the former than the latter, for there is no danger of running the knife into the edge of the wood of the frame, and a single stroke suffices to remove the seal from an entire side of the comb.

In inducing the bees to build thick super-combs, we are not running counter to their instincts, for they will of their own accord build very thick combs where the opportunity offers. I have measured a comb built in a corner of a box, the cells of which were 2¼ inches deep on one side, the other side being only a trifle more than the usual depth.

In addition to the advantages above enumerated, there is another advantage in the deep cells, in the fact that they usually efficiently keep the queen out of the snpers, for she does not lay—can not lay—in deep cells. It is true that if she is short of room, the bees will sometimes cut the cells down to the proper depth for her laying, but this is very exceptional.

My advice for extracting frames in a ten-frame hive is to use not to exceed nine of the former, over the ten brood-combs.

Hancock Co., Ill.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

No. 3.—Some Reminiscences of an Old Bee-Keeper.

BY THADDEUS SMITH.

THE Italian bee was introduced into this country about 1860, or soon after the introduction of the movable-frame hive. I have not the statistics or the history of either event before me to enable me to give the exact dates, and can speak only in a general way from recollection; but both came about the same time, and in so doing gave a new interest in bee-keeping and in bee-literature, and that wonderful impetus to the growth of the business in this country that the last half-century has witnessed.

Many persons engaged in other pursuits—some who had never kept bees, and others who had only a few colonies—now became greatly interested in the subject; and this interest led to an investigation, both theoretical and practical; and as this investigation proceeded some became quite fascinated with the business. The ease with which one could examine the internal economy of the hive with the movable-combs, and to introduce to a colony of native bees a queen of a new race and color, and seeing the natives gradually disappearing until in a few weeks they would all be gone and the new race occupying their places, afforded means of verifying and demonstrating many interesting facts in the natural history of the bee. The short life of a worker-bee in the working season was a revelation that astonished many who always supposed bees lived several years; but the ocular demonstration of this by the introduction of an Italian queen would convince the most skeptical. And so were many other facts in the history of this wonderful insect demonstrated.

This new interest in bees caused by the Italian bee, resulted in adding many new workers to the ranks of bee-keepers. Some thought they would find it a pleasant and profitable occupation in producing honey on a large scale for the market, as the Italians were said, by the vendors, to be greatly superior to the natives as honey-gatherers. Others saw a prospect of gain in rearing queens for sale at prices from \$5 to \$20 each; and the country was soon flooded with queen-breeders until the price got down to one dollar or less, and profits still made at that.

Manufacture of patented and non-patented hives, also sprung up all over the country. An impetus was given to every department of the business. The literary department was greatly augmented, and we had new authors of bee-books, and pamphlets numerous, and many new contributors to the bee-papers from all classes and professions, some of whom have been of great advantage and a blessing to the fraternity.

I think it can safely be said that had it not been for the Italian bee, Mr. A. I. Root would never have gotten up that interest and sustained enthusiasm on the subject that led him to give up a pleasant and profitable occupation to go into the bee-business. And just to think of the consequences! The bee-keeping public would never have seen those wonderfully interesting and instructive letters of "Novice" printed in the early volumes of the American Bee Journal. Gleanings in Bee-Culture would never have appeared; neither would that standard work on the honey-bee—the "A B C of Bee-Culture"—have been printed; nor would those great manufacturing and industrial establishments with all their various branches and departments, be in existence to-day. Under the stimulus of the movable-comb hive and Italian bee, many others were induced to go into the business who became prominent writers for the bee-papers, or large honey-producers and queen-breeders and hive patentees, whose names are worthy of record, and a sketch of their work would be interesting if time and space would permit.

The movable-frame hive caused much rivalry, and some jealousies, between the patentee and vendors, and they spoke and wrote of each other in not very complimentary terms—in fact, in language hardly admissible in polite society; but there were still more rivalry and jealousy, and bickering, between the queen-breeders and sellers of Italian queens that had now sprung up all over the country. The matter of contention was the purity of their queens and their offspring. Each party would contend that he had the only Simon-pure article, and intimate, sometimes in broad assertions, that the bees of competitors were impure and a fraud. Various tests of purity were advocated that added still more confusion to the matter. One writer, greatly perplexed over the matter, said:

"One dealer in Italian bees says 'the workers are distinguished from the natives by a yellow band around the abdomen'; another says,

three yellow bands or rings; a third makes the markings of the queen a test of purity; a fourth tests the purity of a queen by her progeny; and a fifth makes the very amiable disposition of the worker, or the "impeccability of temper," a test of purity. A person entirely unacquainted with Italian bees, after hearing the different opinions of these doctors, if he purchased a queen, purity guaranteed, would hardly know where to look for a reliable test."

As a matter of course, the writer became very much interested in these new bees. I had kept bees all my life, and as soon as I heard of the Langstroth movable-comb hive I adopted it—in 1862 or 1863, I think—and I determined to have some of these new bees.

As I have stated in another article, I came to Pelee Island, Lake Erie, in 1866, and one of the first things I did was to inquire about bees, and I found that there was only one colony on the Island, and I bought that, and went to the main shore of Ontario and bought two more colonies. These I soon had transferred to Langstroth hives. I found that the Island abounded in good bee-pastures, especially the unbroken forest of basswood, and I am a great lover of honey as well as bees.

About this time a number of breeders of Italian queens had come to Kelley's Island, Ohio, because there were no black bees there, and it was beyond the flight of black bees from the main shore, consequently they could rear pure queens without the possibility of having them mated with black drones. Kelley's Island being only a short distance from Pelee Island—just across the international boundary line—I had a fine opportunity to see these bees, and was not long in taking advantage of it. I found a number of queen-breeders there—Aaron Benedict, W. A. Flanders—"Professor" Flanders with his Apiarian Institute and bee-charm; and my friend, Charles Carpenter, one of the earliest settlers of Kelley's Island, and the first person to demonstrate the adaptability of the Island to grape-growing, was also engaged in rearing queens. I paid Mr. Carpenter \$10 for two queens, fine and beautiful ones, of course. I got them home all right and successfully introduced them to two of my colonies.

The humorous side of queen-rearing on Kelley's Island was given by the editor of the Ohio Farmer in his paper in 1867, after a visit to the Island. He tells what he saw there as follows:

W. A. FLANDERS THE BEE-MAN.—Prof. W. A. Flanders—you may have heard of him—has his Apiarian Institute on Kelley's Island, and of course we visited his institution. Mr. Flanders has a host of bee-families dwelling in busy harmony under every green tree in the neighborhood. Talk of big prices for Merino rams! Flanders can get more money for an Italian queen-bee, with three rings around her tail, than any ram-peddler can get for the best Vermont Merino in his flock. Flanders showed us (in a tin of alcohol) one of these amiable little female sovereigns that had lately fallen in a duel with another amiable little female sovereign, for which, he declared with a sigh—which came from as low down as the seat of his broad pantaloons—that he would not have taken 800! Bugs is riz! But then the thing can be settled by arithmetic. Here are 50 other amiable little sovereigns, bred from this insect in the vial, for each of which Flanders can take from \$20 to \$25. The demonstration is plain—a little insect not so big as a toothpick, worth more money than a short-horn bull! The idea would be ridiculous if it were not true. But Flanders has improved upon the original Dr. Jacob Townsend, and instead of being satisfied with the orthodox full-blood Italian with three rings, has gone one better, and showed us a queen of his rearing with four rings around her body, all of the royal purple and gold.

(To be continued.)

In-breeding—If Practiced, It Should Be Sparingly and With Good Judgment.

BY FREDERICK B. SIMPSON.

IT is to be regretted that those friends who have been foremost in agitating the subject of in-breeding, have not yet gone beyond vague generalities, and given us some specific information which would be of direct benefit to the practical bee-keeper. In this connection Mr. A. C. Miller, in May 1 Gleanings, might well make his requirements for a successful queen-bee breeder more complete by adding a college education as another requisite. There is no possible doubt about the great aid these requirements would prove to the queen-rearer; but is it not very exceptional when a bee-keeper possesses all these requirements, and is it not a little unfair to predict failure for all except the exceptionally favored? Is not the commercially successful bee-keeper and queen-rearer practical rather than theoretical, commercial rather than scientific? And can not the best results followed by those who have the educational advantages which make it possible for them to be familiar

with the general laws of biology, and therefore strong on theory but in many cases being prevented from being broadly practical (on a large scale) by reason of occupation or circumstances—can not these students formulate plans based on scientific truth, which the practical man can use as a basis for systematic breeding, making such modifications as future results may indicate—such results to be made known to these students that they may be able to continue to give what aid lies in their power?

In this manner a systematic method followed by a practical man who thoroughly understands all the practical methods of queen-rearing, and who can secure the greatest yield of honey from the greatest number of colonies with the least manipulation, and who can have the best knowledge of the qualities of each individual queen—this man should be able to make the greatest success of queen-rearing and should be able to rear queens so skillfully that no large honey-producer could afford to do anything except requeen from such bred stock. To the end that some such method may eventually be formulated, I will contribute my mite by saying some things about in-breeding; although be it understood from the start that I do not believe we will ever get any really conclusive knowledge on this subject except by *actually breeding the bees*; the more so from the fact that we have nothing in the nature of a domesticated animal which forms any real parallel to the bee.

Herbert Spencer says: "Remembering the fact that among the higher classes of organisms fertilization is always effected by combining the sperm-cell of one individual with the germ-cell of another, and joining with it the fact that among hermaphrodite organisms the germ-cells developed in any individual are usually not fertilized by sperm-cells developed in the same individual, we see reason for thinking that the essential thing in fertilization is the union of specially fitted portions of *different* organisms. If fertilization depended on the peculiar properties of sperm-cell and germ-cell, as such, then in hermaphrodite organisms it would be a matter of indifference whether the united sperm-cells and germ-cells were those of the same individual or those of different individuals. But the circumstance that there exist in such organisms elaborate appliances for mutual fertilization shows that unlikeness of derivation in the united reproductive centers is the desideratum."

Mr. Darwin says: "I will venture to add a few remarks on the general question of close interbreeding. Sexual reproduction is so essentially the same in plants and animals that I think we may fairly apply conclusions drawn from one kingdom to the other. From a long series of experiments on plants, given in my book, 'On the Effects of Cross and Self Fertilization,' the conclusion seems clear that there is no mysterious evil in the mere fact of the nearest relations breeding together; but that the evil follows (independently of inherited disease or weakness) from the circumstances of near relations generally possessing a closely similar constitution. However little we may be able to explain the cause, the facts detailed by me show that the male and female sexual elements must be differentiated to a certain degree in order to unite properly and give birth to a vigorous progeny. Such differentiation of the sexual elements follows from the parents and their ancestors having lived during some generations under different conditions of life.

"The closest interbreeding does not seem to induce variability or a departure from the typical form of the race or family, but it causes loss of size, of constitutional vigor in resisting unfavorable influences, and often of fertility. On the other hand, a cross between plants of the same subvariety, which have been grown during some generations under different conditions, increases to an extraordinary degree the size and vigor of the offspring.

"Some kinds of plants bear self-fertilization much better than others; nevertheless it has been proved that these profit greatly by a cross with fresh stock. So it appears to be with animals, for Shorthorn cattle—perhaps all cattle—can withstand close interbreeding with very little injury; but if they could be crossed with a distinct stock without any loss of their excellent qualities, it would be a most surprising fact if the offspring did not also profit in a very high degree in constitutional vigor."

Until we can get some absolute proof that these arguments are untrue in the specific case of bee-breeding, it would seem unsafe for any queen-bee breeder to do any in-breeding with the intention of selling the resulting stock; but only as a matter of research until some absolute proof could be obtained by experimental work through several generations of bees. Few queen-bee breeders will

consider that they can afford to do even this amount of experimenting in view of the fact that outcrossing has none of the objectional features in the public mind that in-breeding possesses.

One of the bottom facts of in-breeding is, that *Nature* never does it unless compelled to. It is more than likely that in-breeding as originally practiced by man, and in the majority of subsequent cases, has been largely due to the same cause, the absence of an unrelated individual at the time. Also the fact that in distinct breeds, uniformity can usually be accomplished quicker by in-breeding than by outcrossing (where breeds are dependent upon one or a few characteristics, of which vigor, fertility and size are among the least essential) which is a very considerable incentive where it takes several years for an animal to reach maturity. But with bees these two propositions would seem entirely inapplicable; for we seem to be able to obtain an ample number of unrelated individuals of equal value with which to outcross, besides which, the vast number of generations that can be obtained in a short time renders the second reason of little or no force.

Writers in bee-journals have been so prone to allude vaguely to in-breeding in Jersey cattle, and in trotting-horse pedigrees, that a few words on these subjects may not be out of place here, although there being nearly as much pro as con, we can expect little new truth from these sources; especially as in the one case there is almost no parallel to bee-breeding, whereas, in the other, the breed has not been established a sufficient time to secure any amount of uniformity.

The Jersey cow possesses a pleasing color and form—with the frequent exception of her degenerated horns which often require an expert to trim them to a regular shape—and at her best gives a very large quantity of very rich milk, of which a comparatively small amount is required to make a pound of butter or cheese. These are the principal qualities in which she differs from other breeds, and to which she owes any peculiar merit she may possess. To offset these she is very nervous, undersized, very subject to disease and to great mortality in disease, besides which she is extremely deficient in the regular bringing forth of living offspring; and so far as I am able to ascertain, no outcross has yet been found equal to those outcrosses of other breeds in which the Jersey is not a factor. Her good qualities have evidently been brought about at the expense of vigor, fertility and size, for which it seems evident that in-breeding is responsible.

But is the Jersey a fair comparison? *Nature* so situated her in the narrow confines of a small island where eventual in-breeding was inevitable, and therefore is it not possible that *Nature* endowed her with some inherent power by which the evil effects of in-breeding would be mitigated to a certain degree—sufficient with the aid of skillful selection on the part of man, to preserve to us a breed which if left entirely to *Nature* would have long ago become extinct? For on an island of such fertility that animals are staked out instead of being turned loose for pasturing, it would naturally follow that the greatest personal care and attention would be bestowed on such animals so continuously handled.

Then, too, the pedigrees of renowned Jerseys abound in renowned ancestors to so great an extent that it is practically impossible to find a line of demarkation between what has been the result of in-breeding and that which is due to skillful selection independent of in-breeding. And if it had been possible to breed these animals with as much care, to equally desirable unrelated animals, is it not reasonable to suppose (see the quotation from Darwin) that equally good results would have been obtained, not only at no expense of these qualities, but even with an increase in vigor, fertility and size?

With regard to trotting-horses, the general proposition will be found to be true that where in-breeding exists in a good individual that is able quite uniformly to transmit his good qualities to his offspring, such in-breeding is merely an incident of locality or opportunity, and is seldom close, whereas the real cause of quality is skillful selection. Then, too, the sources of trotting families are comparatively few, which renders the incident of in-breeding more frequent than in many others. But this in-breeding, when successful, is seldom close, and, therefore, has but little effect. When trotting-horses were a "fad" they were largely bred with no other quality than that of speed, so that, although speed was often obtained, where we failed to obtain it we had only a failure that did not possess enough other good qualities to make it valuable. But as soon as the "bottom dropped out," the lesson was learned, since

which time our greatest aim has been to produce such an animal as will possess that balance of qualities which will make him the highest typical representative of his species. At any rate we quite uniformly get a high type of horse. If his speed and racing quality are sufficient, we have that which, from our standpoint, is the most valuable. If not of this high grade there may be sufficient quality for a first-class roadster, or an excellent carriage-horse; lacking this, the barbarously inclined can cut off his tail, blind-fold him, and, by training on an inclined plane, behold the highest type of English Hackney! And, finally, if some physical injury should occur we will, often, still have a good individual to breed from.

From all the observations I have personally made where we have done any close in-breeding, in trotting-horses, I am led to believe it is a total failure; except, perhaps, in exceptional cases where two individuals somewhat over-sized, with a tendency towards coarseness, possessing exceptional fertility and vigor, and having immediate ancestors which have uniformly inherited these characteristics for several generations; these individuals, being possessed of about an equal balance of other good qualities, but the good qualities of the one being the complement of those of the other, and vice versa, which qualities should be proved to be hereditary in each pedigree so far as possible. Besides this, the common ancestor, or ancestors, must have proved to be the most successful cross in each case for that animal with which it was mated. Whenever such a case presents itself we will try in-breeding, but in no other.

Here are some cases that have come under my observation: A mare so mated that her offspring had but one grandsire, has uniformly given undersized animals of too fine bone and of no great merit in any respect, although both parents were individually excellent. A stallion that had but one grandsire and whose granddams were half sisters, was quite a fair individual but not possessing any great amount of speed or exceptionally good gait, although apparently physically in perfect health. On examination he was found to secrete not over ten percent of the number of spermatozoa that an average horse did; and it was found that, compared with his chances, he produced not over five percent as many offspring as the average horse. I have not been able to get any information concerning his offspring, but would not be surprised if they proved *absolutely sterile*. Of course, there is one chance in a million that this was due to some unknown cause, but I gave the case sufficient study so that I am satisfied that it was solely due to in-breeding.

Does it not seem reasonable to believe that, in general, in-breeding can be successful only in cases where the merits of the breed depend very largely on only one, or a very few, qualities for which we can profitably sacrifice to a considerable extent, vigor, fertility and size?

In the trotting-horse we can not afford to do this, for we want the best type of horse which is not dependent upon any one or a few qualities. Is not the bee somewhat similar? Will not the best bee get the most honey? Is not the best bee the one that possesses the best balance of good and bad qualities without any necessarily prominent showing of any one quality? The qualifications of a good bee are so complex and variable as to locality, and so interdependent upon each other, that it is very difficult to differentiate them; but, given a good "all round bee," and it is very likely that she will prove herself better in any locality than one that is bred for any one particular quality.

I have written the foregoing on in-breeding, simply because none of the regular contributors to bee-journals have yet shown any desire to give us any specific aid on this subject; and some one should start the ball rolling no matter how incomplete the start may be. Can not those who have had extensive experience in breeding other animals, give us the benefit of their experience and opinions?

Other things being equal, I want long tongues, but if I were rearing my ideal of a bee for sale, the "long-tongue" part of my advertisement would be in smaller type, while with great "scare heads" I would proclaim "Superior Suckers." Above all, I want a bee that can suck and carry as large a load as possible, or else make it up in increased number of loads. To my mind, the long-tongue agitation is too much like treating a *symptom*, instead of the *disease itself*. I believe that long tongues are of value only in so far as they represent an increase in vigor; or, in other words, only when such increased length is the direct result of increased *use* of the tongue, indicating greater activity and vigor. Doubtless the direct issue of the original (priced) queen possessed this increase, but is there not

some question whether the length of tongue may be transmitted without any correspondingly increased vigor, and therefore increased ability to use it?

In conclusion, my opinion, based on the above points, is as follows: Whenever a colony of long-tongued bees is superior to a colony of bees with shorter tongues, as shown by the gathering of nectar from red clover, such superiority is due to increased vigor, which (other things being equal) shows that the greater length of tongue is due to increased use of, and energy in the use of, that member, usually through several generations, it being apparent that it takes more energy to use a long tongue than a shorter one. It naturally follows that in a locality, or at a time when red clover fails to yield nectar, this increased energy of the

HOME APIARY OF GEO. B. WHITCOMB, OF LINN CO., OREG.—See page 450

long-tongued colony will not go to waste but will be used to advantage in the more rapid storing of more easily reached nectar, regardless of its source. And it is quite pertinent to the subject, that the colony which has given me the most nectar to date, this season, from fruit-bloom, contains by far the longest-tongued bees I have, many having a reach of 22-100. And this also is a point in favor of my idea that the best bee is the best regardless of locality. Bee-Keepers' Review. Fulton Co., N. Y.

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

The Premiums offered this week are well worth working for. Look at them.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Catching a Swarm on the Wing.

Is there any way of catching a swarm of bees after they leave the tree they first settled on? If so, what is the quickest and best way? MINNESOTA.

ANSWER.—I suppose you mean is there any way to stop a swarm when it has started to leave. It isn't the easiest thing in the world, but it is always worth trying. Perhaps the best thing is to take a looking-glass, run ahead of them, and reflect the sun upon them. That has been reported successful in driving them back in a number of cases. Some, however, will tell you that a better plan is to have a spray pump and throw a good shower of water upon them.

A Small Queen—Thick Combs.

1. I divided a strong colony of Italians in fruit-bloom, as you suggested some time ago, and the queen-cells started were all small. I left the largest ones, and, when hatched, the queens were not much larger than worker-bees, and leather-colored. I killed one of the queens and put the nucleus back into the old hive, and left the queen in the other division. The queen is two weeks old, and has not commenced to lay yet. Would you advise me to remove her and give them a larger queen? The old colony swarmed two days after I put the nucleus back, and the queen-cells started are large; the queen looks sleek, and is large like her mother.

2. I have considerable trouble getting straight combs, most of the frames having brace and burr combs on them. I don't think the frames were spaced properly when first put in. Would you advise buying an extractor, uncapping the deep ones, spacing the frames over again, and feeding sugar early in the fall? Would it pay me to get an extractor? I am running for comb honey and have eight colonies.

NEW YORK.

— ANSWERS.—1. If a queen does not begin to lay till after she is two weeks old, she will generally turn out very poor, and you will risk very little to kill her.

2. It might pay you to get an extractor, but not for the sake of straightening out your combs. Neither do you need to take any such trouble. If the center of the comb is in the center of the frame, and some of the combs are too thick (which I understand is the case), all you need to do is to keep crowding the combs together a few times on different days. The bees will trim off the parts that touch, all but a few points of attachment which you can remove, and a few operations will make all right. But you will be likely to have some brace-combs in any case.

Finding the Queen, Etc.

I have a very strong colony in an 8-frame hive which I wish to divide and can not find the queen, having looked the frames all over five different times. They have about seven queen-cells, most of them being capped.

1. What is the best way to find the queen?

2. Will a colony swarm if it has laying-workers in the place of a queen?

3. Will the bees build more drone-comb in the spring than in the early fall?

4. Can I divide, and use queen-cells? ILLINOIS.

ANSWERS.—1. Usually all that is necessary is to look somewhat carefully over the frames. Avoid the use of much smoke, for if you smoke the bees till you get them to running, you may about as well give up finding the queen till another time. If you do not find the queen after looking over the frames once or twice, better close the hive and leave them for half an hour or longer. For the queen has probably hidden in such a way that it is impossible for you

to see her, and she will stay hid till the hive is closed up and all is quiet. It may help to put the frames in pairs, using a different hive for each pair. After waiting a very few minutes, you may confidently expect to find the queen between the two frames in one of the pairs. Lift the one nearest you, and as you do so keep your eye on the high side of the frame in the hive, and then examine the farther side of the one in your hand. If you wait long enough, you can tell which pair of frames has the queen, for the bees will show uneasiness, as if missing the queen, in the pairs where she is not.

If you want to make a sure thing of it, use a queen-excluder. Take an empty hive body and put into it one of the frames of brood, after getting all the bees off, or at least enough of the bees so you are sure the queen is not on the comb. Put a queen-excluder over it, and over that an empty hive body. Now brush into this all the bees from the combs, and if they are too slow in going through the excluder into the empty hive below brush or smoke them a little. The queen, not being able to pass through the excluder, will be left in the upper hive.

Often in an ordinary search the queen will escape detection by being among the bees on the side or bottom of the hive while you are wasting your energy by looking over the combs.

But you can not find a queen when none is in the hive, and "seven queen-cells, most of them being capped," forms a ground for pretty strong suspicion that the colony has swarmed and that the queen is gone.

2. You need not fear swarming with laying-workers in place of a queen.

3. Probably.

4. Yes.

Swarm Deserting the Hive.

I have one colony of bees that has acted strangely this spring. It swarmed on Monday while I was in the field, and got away. Then the following Saturday the bees were acting all right at the hive in the morning, but at 11 o'clock, when I came home from town, there were bees all over the house and trees. We sprinkled them with water and they went to the hive, and about 2 o'clock they came out. We put them into a new hive, but about dark they came out again, and we could not find them. We watched them, and the next day about 3 o'clock they came up out of a plum thicket, and went in the direction of the others, right against a strong wind. The last I saw of them they crossed through a hedge, and no one has seen them, so far as I can learn. I have kept bees for years and never had such luck. Now it is a week since the last ones went, and they are acting as if they are going to swarm again. Do you think there were two swarms, or did the first one come back? Why did they not stay in the hive, as it was a new one and is all right, as far as I can see?

SOUTH DAKOTA.

ANSWER.—The probability is that the first time they swarmed it was a prime swarm, and then on Saturday there was a second swarm, the only unusual thing in the case being that it was only five days from the first to the second swarm. If that supposition is correct there will be no more swarming, and the bees are hanging out because the weather is hot and the hive close. When you hived the swarm you ought to have raised the hive and left the cover partly open. They left because it was too hot and close for them.

Swarming Questions.

1. Suppose a colony swarms during the honey-flow, and the old clipped queen is taken away, how many days before the old colony will swarm again?

2. Is the young queen of the old colony fertilized before the second swarm issues?

ILLINOIS.

ANSWERS.—1. Generally in about eight days, but if the weather had been severe for some days before the time of the first swarm so as to delay it, that would make the time just so much shorter from the time of the first to the next swarming. If the first swarm should occur before the usual time (at the sealing of the first queen-cell) the second swarm would be delayed to that extent.

2. No. When the second swarm issues, a young queen issues with the swarm, and the young queen that is to reign as the mother colony is still in her cell, so of course could not be fertilized.

Some Swarming Troubles.

Will a colony of bees swarm without a queen? I assisted my father in hiving two swarms of bees this spring. The first swarm we put into a clean new hive with foundation ready for work. They stayed three hours and then left the hive, and we hived them three times in the course of the day, and each time in a new hive. The third time they moved out as quickly as they would, all right. We looked them over and could not find the queen, and before we could hive them again they all started for the timber.

The second swarm we hived twice, and the third time we put a comb of honey in the hive and shut the entrance, and put them down cellar over night. The next morning they were all dead but about a pint, and we could not find a queen among them. What do you think was the cause?

"LAURA."

ANSWER.—I knew one case in which a swarm issued when there was no queen in the hive. But I had removed the queen from the hive only a short time before, and I suppose the bees had not yet learned of her absence. So it is safe to say that a swarm will not issue from a hive without they have, or suppose they have, a queen present. But even should a swarm issue in such very exceptional case without a queen, they will not go off without a queen, but will return to their hive or to some other hive in the apiary. It is not always easy to find a queen in a swarm, and the likelihood is that there was a queen present.

The probable trouble was that the weather was very hot and you did not shade and ventilate the hive. Putting that swarm in the cellar was not a bad stroke, but you probably shut them up so tight that they smothered. After putting them in the dark cellar you should have given them a very large entrance, raising the hive well. A frame of brood is better than a frame of honey to give to a swarm.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

FINGER-TICH FOR RECONSTRUCTING.

What shall be done to me for my everlasting needlessness? Can't see a good thing without finger-tich to see if I can't make it better by reconstructing it. Now there's the striking verse on little neglects, which W. Z. Hutchinson quotes to open his excellent paper on page 327. I want it to run:

"For the want of a nail the shoe was lost;
For the want of a shoe the horse was lost;
For the want of a horse the rider was lost;
And a friend his slain friend did bewail
When he might have been saved by a horseshoe nail—
And, if that rider had been De Wet,
A nation lost in the end we'd get.

STING-POISON IN HONEY.

And so (according to page 334) in each 62 pounds of honey the bees put an ounce of sting-poison. The German writer didn't think of the thing in that shape, or the enormity of the pilgrim he would have halted him from passing it on. Although it is the same thing, it looks much more believable to say 0.1 percent. For all the bad company it is in, the statement that sting-poison is probably a non-volatile alkaloid dissolved in volatile but rather harmless fluids, may very well be correct. But even on that we must remember that breathing the volatile part has a very bad effect on some persons.

DEET-TUBED ALSIKE AND WHITE CLOVER.

E. R. Root contributes a good point in a red-hot controversy when he says he has seen both alsike and white clover too deet-tubed for average bees to fully reach bottom. Page 343.

PARTHENOGENESIS.

It was more than a hundred years after Columbus sailed before so wide-spread and vitally important a truth as the circulation of the blood was discovered! It's amazing. And one of the constituents of the atmosphere remained undiscovered until the American Bee Journal had become an old paper. Why should man, a reasoning creature, be so great in fantas-

tive uses of his reason and so small in common-sense applications? We need not specially wonder, therefore, that Parthenogenesis among bees was late in being discovered, or that an occasional "Thomas" turns up even now. Page 359.

NOVEL PARTNERSHIPS.

It is a little in the line of a novelty to find four families in joint ownership of a cow. And eight families each taking a different magazine, and passing it on weekly are certainly getting a great deal for a little money—if the partnership is not wrecked by some wrong-doing of its sailors. When sons are sufficiently cultured, Prof. Cook, many new, as well as old, partnerships can be sailed without wreck and without injustice. A family worship with the scripture lesson recited instead of read is certainly a remarkable and pleasant novelty. Page 361.

MOVING WIDE-OPEN HIVES WITH BEES.

Glad to see A. D. D. Wood advocate liberty for bees while being hauled from place to place. I have seen a little of this. Possibly it may not be practical for a big two-horse wagon load; but for one or two colonies to be taken in a buggy I am quite sure it is much the better to let them have their door wide open. Smoke them just enough before starting, and keep the smoker ready for action on the road. Page 363.

SHOOTING SHOT INTO SWARMS.

Shooting charges of fine shot through a high-minded cluster till the queen is killed and the cluster broken up—well, it is somewhat ingenious; but I do not understand it to be preached for general practice. Certainly not "twen, cen." Interesting to see they could not be jarred lower by any kind of bunting. Cousins to my bees, I reckon—and swarms have been unusually high-minded the present season. Page 364.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

ORDER.

I doubt if "Order is heaven's first law;" but I have no doubt that it is so well up to the front that whoever first asserted it got nearer the truth than most of us do. A more homely phrase was sounded in our ears, or ought to have been, even from the cradle, viz.: "A place for everything and everything in its place." I wonder if more energy is lost anywhere else in life's experience than in looking for things. We put things anywhere, and must, as a consequence, look everywhere when we want them. What a saving to the world if in all our home circles were taught order.

I have an assistant in my laboratory. He is a gem. First, he is a model of industry—always at work, and at good work. How much that means in any life. Yoke such habit to any life and that one becomes a rich storehouse of precious truths. More, my assistant is a very scholarly man. He graduated at the Indiana University, took a second degree at Stanford University, and last a Ph. D. at one of the German universities, and yet he was of a family of no wealth. What a glorious country. I mean glorious, as much as that word means. A poor boy of parts can secure, all unaided, the best education. It seems to me that were I to live my life over again, I would do just as Dr. Shaw did. Life is too good a thing—too responsible, as God looks at it—to be entered into with any but the best preparation. Yet Dr. Shaw's culture is not his most telling characteristic. He has system in all his work. Our laboratories are large. We have apparatus with all kinds of reagents, stains, instruments—hundreds of things. At a minute's notice Dr. Shaw invariably places the desired thing right in my hand. Little time is lost in hunting for things in our work-rooms.

We often wonder how some people can accomplish so much. The secret lies in just this habit of order. No home circle can afford to minimize its importance. Has each of our children his room, his drawers, his closet? Do we as mothers, and fathers, look to see that these are always in order? We may sometimes think that this takes time and effort, that we in our hurry and press of life's burdens can't afford; but for our own good, for our own future peace of

mind, we can not afford to neglect it. The very success of the dear ones God has given us may turn, very likely will, on just this point.

It is often said that the competition in life is constantly becoming more and more severe. That likely is true. But it is even more true that the competition is very slight among those thoroughly prepared to do the work that comes to them. And in almost all lines the habit of perfect order, of thorough system in all work and action, will stand up among the first in importance.

I have no hesitation in saying to any young man, "You need have no worry—not the least anxiety—as to a good position in any line of useful work, if you are well fitted. In all lines the thoroughly competent man is at a big premium.

Let us all work to inspire our dear children to this perfect preparation. Urge early that they know how to do, that they shall be interested, enthusiastic to do their best, their very best, in all their work. And never neglect to teach them that if order is not success's first law, it is a very close second.

A very able and successful college president once said to me: "I can go into my library in the dark and take down any book I may wish to use." I always wondered if he could. Yet I knew him well, and if he were not wholly correct, the assertion marked a characteristic which did much to lift him to the high position which he so successfully maintained for many years.

PETS.

In our busy lives, I wonder if we are as careful as we should be to see to it that our homes are cheered and enlivened by numerous pets. We have two little kittens now in our home. They are so full of their antics that they have won all our hearts. We all are so thoroughly interested in them that they receive very careful consideration. Nothing in the home is too good for "Kitty Clyde" or "Kit Carson." I often wonder as I see people harsh to their faithful horses and cattle, what their bringing up was. Did they have pets when little? and were they led to care for them as our wee kittens are cared for? I doubt if in our country the watch-dog is of much account as a watch-dog. I am as sure that mousling is not the kitten's best use. Then let dog or cat, horse, cow or bird, have its best use in awakening and developing the sympathies, in quickening the affections and calling out that love and thoughtful care that is the best establishment in any life. Is it Eliza Cook that says in speaking of our pets of the home?

"And if to us one precious thing

Not theirs—a soul—is given,

Kindness to them will be a wing

To bear it up to heaven."

I have a feeling that my horse and cow are happier and feel safer when I am around. I know they are a pleasure to me, and that I am a better man for caring for them. Even the ants have pets in their homes, and they are the wisest among insects. May we not say truly that the wisest people will have numerous pets for their children?

KIND WORDS IN THE HOME.

I know of one of the most spiritually minded Christian ministers that I have ever known, who believes that if we brought up our children as we should, they would need no change of heart. They would be right-minded and true to the sweetest and purest in life from childhood up. I wonder if harsh, unkind words are ever in place in the home. The ones who have influenced me most sweetly and truly never come at me with harsh words or bitter speech. I have taught school ever since I was fifteen years of age. I never yet used a whip. I have sometimes lashed with my tongue. I have often wondered if such scourging was not almost always evil. I have a sort of theory that if we have love enough for our dear ones, we may push the harsh word and fault-finding tone out of the house, to the betterment of all left within. But we must be sweet ourselves always if we would win by this better way.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

To Our Shippers.

About May 1st last, we removed our business from the buildings 120-122 W. Broadway to larger and more commodious quarters at Nos. 265-267 Greenwich St., and 82, 84, 86 Murray St., and we duly sent to our friends in the trade a notice of our removal. Shortly after we vacated the premises (120-122 W. Broadway,) one Joseph M. McCaul, rented a portion of our old quarters, and hung out a sign, "Hildreth, McCaul Co., Jos. M. McCaul, Prop.," with other large signs to the effect that his business is "headquarters for honey, beeswax, maple sugar and maple syrup."

The mercantile agencies report that Jos. M. McCaul is the sole proprietor of the new business, and that he claims to have paid to one Henry P. Hildreth (who has no connection with our business,) a consideration for the use of his name.

We will not comment upon the act of leasing our old quarters and exposing thereon the sign, "Hildreth, McCaul Co.," further than to state that we have instructed our attorneys to apply for an injunction restraining the said McCaul from using the name of "Hildreth" in connection with his business in any manner whatsoever.

We value highly the good name and business we have established by many years of satisfactory dealing with our friends in the trade, and we therefore send this notice so that you may not possibly confound us in any manner with the so-called "Hildreth, McCaul Co."

Our firm name remains as heretofore, and all our business is carried on at our new quarters—

Bees Doing Well.

Bees have been doing well since June 1. I have a hive on scales which is 120 pounds heavier now than it was then; the colony has had extracting-combs to store in, and has not swarmed. There have been four days when the bees of that colony stored 8 pounds per day. The honey is very fine, being all from white clover.

SWARMS have issued from all colonies worked for comb honey. J. L. STROGO, Page Co., Iowa, June 28.

Bees Working on White Clover.

We have had a busy time this spring and summer looking after our fruit and our apiary.

I put 25 colonies of bees into the cellar last fall, and took out the same number this spring, most of them in fine condition. Three or four of them were a little weak, but I soon strengthened them by feeding for a few days, and the early bloom helped to get them in good condition. The bees throughout this part of Iowa were extra-strong in numbers when the white clover came into bloom. I believe we are having the heaviest crop of white clover we ever had in the State, and the bees have been making it count, both in swarming and in storing fine honey.

J. W. SANDERS, Marshall Co., Iowa, July 4.

Swarms Selecting a Home—Uniting.

I have been handling bees for about three years, commencing with three colonies which I made friends with me. I got the "ABC of Bee-Culture," Dr. Miller's "A Year Among the Bees," Prof. Cook's work on bees, and several other books, and also subscribed for the American Bee Journal. I now have about 40 colonies, and find the study a most interesting one.

I make all my own hives. The first year I made box-cups, 14x12 inches, inside measure, and 10 inches deep. The style of hive I am now using is 14", 12", and 9", inches deep, inside measure. A larger hive than this it would take the bees two years to fill up below, as this is no bee-country.

On pages 35d and 35s of the American Bee Journal I find an article by A. P. Raymond on swarms selecting a location, and whether they select it before or after they issue. Of course, every bee-keeper has his own opinion on the subject; I will not express mine, but I will relate a freak of my bees along this line. I was in my apiary about 10 A.M. when a swarm issued. After the usual excitement about half of the swarm clustered, and the other half took to the woods. This confused me a little, but I finally concluded to give the part that had clustered, thinking that perhaps the queen was just as likely to be with them as with the part that had left. After hiving them I decided to follow in the direction the runways had gone, hoping that I might locate them in a small piece of woodland, where they were last seen. After hunting for some time I found what I took to be my runaways up in a large poplar tree, going in and out of a knot-hole. This tree was on a bee-line from the hive they had just left.

I went home regretting the loss of the bees, but consoling myself with the thought that I had half of them at home safely hived. Everything went along smoothly until about 2 or 3 o'clock in the afternoon, when this half-swarm came both in great excitement, and after circling about for a few minutes they, too, took to the woods, and in the same direction the first ones had gone. It seemed to me that they were making for the same place, so I kept pretty close behind them, as the distance was not over 300 yards, and along an open route. They finally reached the old

16 25A3t

poplar and joined the others. Then I was convinced that the bees I first found in the poplar tree were not runaway.

Bear in mind that it was 10 or 11 o'clock when the first swarm left, and 2 or 3 o'clock when the others joined them, making from 1 to 6 hours between the leaving of the first and the second lot of bees.

Now, then, here is an instance which contradicts both theories, one about bees first clustering to let the queen rest, and the one in regard to their selecting their future home before swarming, as one-half of the swarm clustered and the other half "lit out" without clustering.

My opinion on the subject, based on my own experience and what I have read, is that whenever they do select their future home it is before swarming, but I think the very frequently issue without having selected a home. My experience has been that about one swarm out of every 25 leaves without clustering. A friend of mine, some distance from me, tells me that his bees acted very strangely this year, nearly every other swarm leaving without clustering at all.

Mr. Raymond says—or at least we are to infer that he says—that the virgin queens can and do always fly without having to rest, and that it is the old queen that the swarm has to give time to rest. I had supposed from my own experience that just the reverse was true, for I have frequently found a young queen trying to fly and join an after-swarm. Sometimes they could not rise, and I have occasionally picked them up, and either put them back into the hive or into a bottle until I could hire the swarm, and I would release the queen as the bees were going in. But I do not remember ever seeing a prime swarm with a queen that had to be assisted or cared for. One thing is certain, and that is, that with each prime swarm there is an old or fertile queen, and with after-swarms there is a young and unfertile queen. I have frequently found such a queen hopping about in front of the hive trying to fly, and have returned her to the original hive. There is no telling how many such queens get lost or destroyed, for the hive is often too high for her to crawl back to the entrance.

As the subject of prevention of swarming seems to be an all-important one now among bee-keepers, I would like to ask why it can not be done in the following way: Whenever an after-swarm issues, manage to catch the queen and either bottle her up for use somewhere else, or destroy her, and return the bees to the old hive, where they will be received without any doubt. Does this not prevent increase and swarming in a very simple and practical way, as we know the bees will not leave without a queen?

I notice that some writers claim it to be a very simple thing to unite two small colonies successfully where each has a queen, but I have not found it so. It is anything but simple and easy. Of course, I can do it, but they go to fighting and killing each other, and that I dislike more than anything I know, unless it be to crush a lot of bees myself when working with them.

I wish some experienced bee-keeper would reply to this, and at the same time give the

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers one ounce of the seed for sending us ONE NEW subscriber to the American Bee Journal for a year with \$1.00; or will mail to any one an ounce of the seed and the American Bee Journal one year—both for \$1.30; or will mail an ounce of the seed alone for 50 cents. As our stock of this seed is very small, better order soon.

best plan to unite two or more weak colonies, where each has a queen and some comb and honey. I desire to unite some of mine before fall, as that is the only way I know of to prevent the moth and miller from destroying them. According to my experience, no bee-keeper can have his colonies too strong, whether he is working his bees for profit or pleasure. The stronger the better, and one extra-strong colony is worth about three ordinary colonies, everything else being equal. Such a colony will be able to give the owner more honey than three weak ones, which are almost certain to be destroyed by the moth along in July or August. I have seen some weak colonies build up to a respectable size, but it was a hard pull before they stored any surplus honey, and it is the surplus we bee-keepers are after, I believe.

JOHN KENNEDY.

Adams Co., Miss., June 12.

Winds Cut Honey Crop Short.

Our crop is about 20 or 25 pounds to the colony of extracted honey. Hot, dry winds dried up the bass-wood and clover, on short notice this year.

F. F. ZILLMER.

Grant Co., Wis., July 6.

A Downpour of Sweets.

Williamson County, in which we did not drown the elephant last spring, is now receiving a heavy downpour of sweets, and we believe that the flow now on is the heaviest since 1897 or 1898. We have every prospect that it will continue until frost. Bee-keepers are smiling a regular "bee-smile."

O. P. HYDE & SONS.

Williamson Co., Tex., July 6.

Long-Tongued Queens and Red Clover.

Considerable has been said, *pro* and *con*, about long-tongued queens. Why not get some red clover seed from Sweden? A man who was born there told me that the bees work on red clover there all the time.

Bees are doing pretty well now. There is lots of white clover, and it is full of nectar.

A. ANDERSON.

Greene Co., Iowa, June 25.

Outlook Discouraging.

The outlook for a honey crop in this locality is very discouraging. It has been so dry, and there have been such hot winds, that there are scarcely any flowers in bloom, although the bees are bringing in some honey from alfalfa.

A good many colonies starved to death last winter. The spring was cool and wet until about May 1. There is some surplus being stored along the creek bottoms, but none in the uplands.

R. C. STEPE.

Woodson Co., Kans., July 6.

Losses Heavy—Large Yields Per Colony.

Our losses were heavy last winter. On account of the mild weather bees flew most of the time, and therefore became weak, and died from spring dwindling. I lost 25 out of 150 colonies in this way, sold 25, and 24 were queenless, leaving 76, spring count, as none that were queenless have built up so as to store any surplus.

All colonies that were strong early in the season have done remarkably well, considering the fact that basswood did not yield on account of hot winds and dry weather; white clover secreted well during the early part of June, but is now yielding very little, if any. Catnip is about the only source from which we are getting any honey, and it is not yielding as profusely as last season.

The greatest yield of extracted honey from one colony up to July 1, is 400 pounds; another has finished 265 one-pound sections.

We are not expecting a fall flow, as the extremely hot weather has prevented the growth of the fall nectar-secreting plants.

J. L. GARDNER.

Richardson Co., Neb., July 1.

The Bee-Keeper's Guide;

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without *THE BEE-KEEPER'S GUIDE*.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year.

Send us TWO NEW SUBSCRIBERS to the Bee Journal with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

144 & 146 Erie Street.

CHICAGO, ILL.

QUEENS

QUIRIN THE QUEEN-BREEDER has now on hand, ready to mail, 500 young, long-tongued Red Clover Queens, Golden or Leather Colored.

We have one of Root's best breeders from his 2nd, long-tongued, Red Clover Queen, and a Golden Breeder which we are told is worth \$100, if there is a queen in the U. S. worth that sum.

J. L. Gandy, of Humboldt, Neb., tells us that the colony having one of our queens, stored over 400 pounds mostly comb honey in a single season. A. I. Root's folks say that our queens are extra fine, while the editor of the American Bee Journal tells us that he has good reports from our stock from time to time.

We have years of experience in mailing and rearing Queens. Queens positively by return mail from now on. Prices for balance of season as follows:

	1	6	12
Selected	\$.75	\$ 4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected tested	1.50	8.00	

Extra selected tested, the best that money can buy, 5.00

Foundation Sagging in Brood-Frames

C. Davenport describes in *Gleanings in Bee-Culture* his plan to prevent this, which does not require wiring nor splints, as follows:

This sagging or stretching of the foundation, as those who have had trouble in this respect know, is next to the top-bar, a strip two or three inches wide. After foundation has been fastened in a frame, and while it still remains in position on the board, the point of a wax-dropper is held close up to the foundation, two or three inches above the top-bar; then a small stream of wax is forced out. As the point is lowered to the top-bar, this adheres to the foundation; and if the operation is repeated at intervals the whole length of the top-bar, it will prevent the foundation stretching when the bees first get on it; and by the time they do, these strips of wax off the foundation are usually drawn out enough to hold it from sagging.

Hive-Covers and Bottom-Boards.

W. W. Somerford says in *Gleanings in Bee-Culture* that he prefers the plain reversible board cover for the climate of Cuba. Because it is cheaper, and because they warp with less force, he uses boards 3/4-inch thick. In preference to thicker.

His bottom-boards are somewhat novel. After struggling with difficulties connected with ordinary bottom-boards, he says:

I scratched my head, got on my wheel, and started off with a Spanish-speaking American bee-keeper to a tile-brick factory. We soon found the jolly owner, and told him just what we wanted—smooth and straight flat-pressed brick, 16 inches wide by 21 long. He smiled, and said he had just the "American machine" to make them with, and made them. And, gentlemen, I can tell you now, as I place them on nice, flat ridges of earth, it is with a feeling that I shall be grown old and gray before the meanest one begins even to show decay. The man who made them said they would last forever. Just think of a nice bottom-board lasting forever, and costing only 10 cents! If you have no tile factory to apply to, concrete or cement will make them even cooler than the coolest in summer, and warmer than the warmest in winter.

Some Things About Queen-Rearing.

The following conversation, taken from the Australian Bee-Keeper, will interest beginners:

Fred.—I say, Will, you have introduced 24 queen-cells to-day, will they be laying in 10 days? I think you said a queen commences to lay in 10 days.

Will.—Yes, Fred, I suppose I did say so, but those were not queens I distributed, but queen-cells, and most of them will not emerge until to-night, so I will count full 10 days from then, *i. e.*, I will expect to find them laying on the eleventh day, and will look them up after that time.

"Will you not look at the nuclei before then?"

"Oh, yes, I will make sure the cell has not been destroyed. I will look up the virgin queens in about two days, and if I find them I will not disturb them before the eleventh day."

"Have you any object in not looking through them often?"

"Yes, I have, and if it were not for the frequent loss of queen-cells I would prefer not to touch the boxes until the queen was due to hatch. My rule is, *don't* disturb any hive having a virgin queen, first, it is an unnecessary loss of time, and, secondly, the young queen often gets excited on the opening of

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00.

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

the hive and rushes over the comb; the bees chase her, and the result is she is balled and probably killed."

"Is the queen always to blame for the loss in getting excited?"

"No, not always. There is something about a colony of bees having a virgin queen that makes them different from other colonies, and these colonies require great care and cautious manipulation. Sometimes the bees are not contented to wait until nature requires a queen to make her wedding-flight, but seem intent on driving the virgin out of the hive. There are other bees that will tear down every cell given them, and others that will ball their queen, whether laying or virgin, every time the hive is opened."

"Do you get many colonies that give you trouble in that way?"

"It may not be often such trouble arises, but when it does I frequently find more than one nucleus so disposed, and usually trace it to the whole of the bees having been taken from one colony to form nuclei."

"If you have such troubles you must lose a few queens."

"Certainly. If I could only get 50 percent of my virgin queens mated and laying every year I would consider I did well. Some years I do much better, and others worse."

"Would there be a greater loss than 30 percent?"

"Oh, yes, during some seasons; if there is no honey being stored the loss might be 50 percent or more during certain portions of the season. I frequently have had almost total losses of several batches of cells distributed. This would occur very early in spring when there was a return of almost wintry weather, chiefly cold winds. The results depend greatly upon the season. During the past season I had excellent results, almost every cell producing a queen; but then honey was plentiful."

"I always thought the prices charged for queens were too high, and to tell you the truth, I intended to rear queens to sell after I got a little practice. I can now see that it is not all gold that glitters."

Cold Winters and Brood-Rearing.

A Stray Straw in Gleanings in Bee-Culture says:

The colder the weather in winter the warmer the center of the cluster. That being the case, theory would lead us to expect brood-rearing earlier in cold than in warm winters. I've often wondered whether that theory was indorsed by practice. Now comes L. Stachhausen, in the Southern Queen and says: "When I kept bees in a cold climate, more than 30 years ago, I observed in outdoor wintering that, the colder the winter the earlier brood-rearing commenced."

Section-Honey Without Separators.

Editor Root says in Gleanings in Bee-Culture:

I once heard an extensive bee-keeper get up in convention and say he had no use for separators—that he could and did dispense with them; and what was more, he got just as good prices for his non-separated honey as he did for that produced with them. It so happened that, months afterward, I ran across some of this man's non-separated honey; and, of all the "kicks" I heard from the buyer! The long and short of it was, he would never buy any more of that honey again. It was too crooked, too bulged, too everything; so when I hear a non-separator man talk, I wonder whether he holds his trade.

Bees That Are Rustlers.

E. H. Schaeffle says in Gleanings in Bee-Culture:

At present the efforts of the queen-breeders seem to be confined to stretching the tongues of their stock to the utmost limit. While this elongating of the bee's tongue may be of benefit to those bee-keepers living in red clover sections, to the average apiarist the working qualities of the bee are of far more

Please Mention the Bee Journal when writing Advertisers.....

importance. It is a well-known fact that some colonies of bees will put up several hundred pounds of honey in a season, while others in the same apiary will not give a pound of surplus. I hold that the bee wanted is one that will give the most honey under average conditions. When I sit down by one of my best colonies and compare its movements with that of the average colony, I find that the rustlers come out of the hive on the run, stop an instant to gather themselves for the spring, and then are away like a bullet. Turning to the average colony I see that the bees come out leisurely, slowly crawl half way up the front of the hive, stop for the spring, and then, springing out slowly, circle and leisurely wing their way to the fields. Returning, the rustlers come down on the alighting-board with a bounce, and rush into the hive as though the queen's business could not wait, while the bees of the average colony drop on the alighting-board exhausted, rest there for several seconds, and then slowly crawl into the hive.

Now, I can not go with the bees to the "fields and far away," but it is safe to assume that they work in the field as they do at the hive. If this is the case, the rustlers will make two trips to the sugarbush's one. Here, we can, by careful selection, produce a strain of rustlers just as the fast trotter has been developed.

Red Clover Queens!

Bred from a daughter of the A. I. Root Co. long-tongued \$30.00 Queen, and mated in my apiary where there is nothing but the best Italian stock.

I have drones flying in my apiary from seven different States. Untested, \$5 each, \$5.50 per dozen. Safe arrival.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.

Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman. This nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—The Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Chas. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full description of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings, and is especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 250 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienen-rucht und Vergewinnung, nach der neuesten methode, von Th. G. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 30 cents.

Bee-keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper.

Bee-keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 25 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEwey Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cents.

Foul Brood Treatment, by Prof. F. R. Ceshire.—Its Cause and Prevention. Price, 10 cents.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Cappings and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about capping fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Poultry, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Treats everything about Poultry Business. 64 pages. Price, 20 cents.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 8.—The new honey is arriving, and some nice lots of white clover comb have sold at 16c per pound. The urgent demand has been supplied, which is very tight at this season of the year, and we find shipments beginning to accumulate so that 15c would be accepted if offered; amber grades are nominal at 12 to 13c. Extracted, white, is selling slowly at 75¢ per lb.; amber, 50¢ to 55¢, according to b. l. flavor, and style of packaging. Beeswax, 30 cents for choice yellow.

R. A. BURNETT & Co.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from 1/2 to 1 cent per pound.

C. H. W. WEBER.

BOSTON, June 29.—There is practically no comb honey in our market, and owing to warm weather very little call for it. Are expecting some new comb early next month. Market for extracted dull, at 6 1/2¢.

BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00.

PREVIER BROS.

NEW YORK, July 8.—Our market is practically bare of comb honey, and demand good for white comb. Fancy stock sells readily at 13¢. No. 1 white at from 13 1/2¢ to 14c, and amber at 11 1/2¢ to 12c. Extracted not in much demand, with plenty of supply; white, 60¢ to 65¢; light amber, 55¢; dark, 45¢ to 50¢. Beeswax firm at 21c.

HILDRETH & SEGELKAR.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts or stocks and little demand. It is between seasons now. Prospect of good crop in this vicinity from what bees there are left, the greater portion having been killed by foul brood exterminators. H. R. WRIGHT.

DETROIT, June 27.—Very little old honey in market, and no new honey come in yet. Splendid showing for good stock at 15¢ for best grade No. 1 Colorado. Amber, 13c. Beeswax firm at 20¢ to 21c.

M. H. HUNT & SON.

BUFFALO, July 10.—No demand for honey yet unless a very small amount of fancy white at perhaps 15¢ to 16c. Some old lots still about, unsalable, almost, at 6, 8 and 10 cents. Beeswax, 22¢ to 23c.

BATTERSON & Co.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being granulated. Sales are light at 15¢ for best grade No. 1 Colorado. Amber, 13c. Beeswax firm at 20¢ to 21c.

W. R. CROMWELL PRODUCE CO.

Successors to C. C. Clemons & Co.

SAN FRANCISCO, June 19.—White comb, 11 1/2¢ to 12 1/2¢; cases, amber, 10¢ to 11c; dark, 6¢ to 8c. Extracted, white, 55¢ to 60¢; light amber, 4¢ to 4 1/2¢; amber, 3 1/2¢ to 4c. Beeswax, 26¢ to 28c.

Market shows no quotable improvement, but there are no large quantities obtainable at the prices generally named. Sales are light at 15¢ for best grade No. 1 Colorado. Amber, 13c. Beeswax firm at 20¢ to 21c.

Wanted Fancy White Comb Honey in no-drip cases; also Extracted Honey. State price, delivered. We pay shipping. F. W. M. H. & Co., Front & Walnut Sts., Cincinnati, Ohio. Reference—German National Bank, Cincinnati.

Sweet Clover (yellow)....	\$1.50	2.80	6.25	12.00
Alfalfa Clover.....	90c	1.70	3.75	7.00
White Clover.....	90c	1.70	4.00	7.50
Alfalfa Clover.....	80c	1.40	3.25	6.00
Japanese Buckwheat.....	30c	.50	1.00	1.60

Prices subject to market changes.

Single pound 5 cents more than the 5-pound
rate, and 10 cents extra for postage and sack.

Add 25 cents to your order, for cartage, if
wanted by freight, or 10 cents per pound if
wanted by mail.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

I ARISE

To say to the readers of
the BEE JOURNAL that
DOOLITTLE...

has concluded to sell
QUEENS in their season
during 1901, at the fol-
lowing prices:

1 Untested Queen.....	\$1.00
3 Untested Queens.....	2.25
1 Tested Queen.....	1.25
3 Tested Queens.....	3.00
1 select tested queen.....	1.50
3 " " Queens.....	4.00
Select Tested Queen, last year's rearing.....	2.50
Extra selected breed- ing, the very best.....	5.00

Circular free, giving particulars regarding
each class of Queens, conditions, etc. Address,

G. M. DOOLITTLE,

Borodino, Onondaga Co., N. Y.

Please mention Bee Journal when writing.

24th Year Dadant's Foundation. 24th Year

We guarantee
satisfaction. **

What more can anybody do? BEAUTY,
PURITY, FIRMNESS, No SAGGING, No
LOSS.
PATENT WEED-PROCESS SHEETING.

Why does it sell
so well? **

Because it has always given better satis-
faction than any other.
Because in 23 years there have not been any
complaints, but thousands of compli-
ments.

Send name for our Catalog, Samples of Foundation and Veil Material.
We sell the best Veils, cotton or silk.

BEE-KEEPERS' SUPPLIES OF ALL KINDS.

Very fine pure-bred BARRED PLYMOUTH ROCK Chickens and Eggs
for sale at very low prices.

Langstroth on the Honey-Bee-Revised,

The classic in Bee-Culture—Price, \$1.25, by mail.

Beeswax wanted at all times.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

Please mention Bee Journal when writing.

Red Clover Queens

We have been telling you through our advertisements of the
superior stock of queens we are furnishing this year, and we have
abundant testimony from others corroborating our opinion.
Look at the following which is only one of the numerous endorse-
ments received.

July 5, 1901.

The bees are working as I never saw them work before, and
already there is over 100 pounds of honey in the hive, and all
from clover. I am led to believe that long tongues and good
working qualities go together.

Yours very truly, OREL L. HERSHISER,

Supt. N. Y. State Apianian Exhibit, Agricultural Building,
Pan-American Exposition, Buffalo, N. Y.

This refers to a colony of bees on the Pan-American grounds
with one of our Tested Red Clover Queens reared last season.

Our Prices are as follows:

Gleanings in Bee-Culture one year and one Untested Red
Clover Queen, \$2.00.

Gleanings in Bee-Culture one year with Tested Red Clover
Queen, \$4.00.

Gleanings in Bee-Culture one year with Select Tested Red
Clover Queen, \$6.00.

If you want something good you can not do better than to
order one of these queens. All orders are filled promptly. No
extra postage on these offers to foreign countries.

IMPORTANT NOTICES.

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50 cents a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "dec 01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts.—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

National Bee Keepers' Association**OBJECTS:**

To promote and protect the interests of its members.

To prevent the adulteration of honey.

To prosecute dishonest honey-dealers.

BOARD OF DIRECTORS.

E. WHITCOMB,	THOS. G. NEWMAN,
W. Z. HUTCHINSON,	G. M. DOOLITTLE,
A. I. ROOT,	W. F. MARKS,
E. T. ABBOTT,	W. M. HAMBAT'GH,

E. R. ROOT,	DR. C. C. MILLER.

EXECUTIVE COMMITTEE.

ERNEST R. ROOT, President.
R. C. ATKIN, Vice-President.
DR. A. B. MASON, Secretary, Toledo, Ohio.

EGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

☞ If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one (of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

MR. F. B. SIMPSON, whose article on in-breeding appeared in last week's number of this journal, desires to make the following correction:

I wish here to correct the error I made in my article on in-breeding, on page 452. When I wrote, "My idea that the best bee is the best regardless of locality," I had in mind all the limitations mentioned in the 4th full paragraph in the 2d column on page 454, but failed to put them on paper, as they should have been if again mentioned, for I am a long way from believing the way the last sentence was printed. F. B. SIMPSON.

EDITOR E. R. ROOT passed through Chicago on his homeward journey Monday evening, July 15, stopping in the city only between trains. He had covered about 6000 miles, making some 45 stops, and was feeling well, having gained several pounds in avoirdupois. "The Texas" bee-keepers' paradise," mentioned by him in a recent editorial item in his paper, is already greatly overstocked with bees and bee-keepers, so no one need get ready to move there right away. In Colorado and Utah, however, there are unoccupied locations that are excellent for bee-keeping.

LONG-TONGUED HONEY-BEES—I am making a study of the length of tongue in the honey-bee, and its relation to honey-production. I shall be glad to have all readers of the American Bee Journal, who are interested in the subject, send me bees from their best and their poorest colonies for honey-production. Send not less than 10 or 15 alive in a queen-cage. Do not put bees from different colonies in the same cage, and do not send bees from colonies where a new queen has been introduced this season, unless within two weeks, as it will be best to have all the bees in a cage from the same queen. If any have bees from queens that have been recommended to produce specially long-tongued stock, I shall be glad to receive some of the bees and measure their tongues. Send full information with each lot of bees. I shall be glad if some can send specimens of the German or black bee, also Carniolans, Cyprians, and Syrians. Address, C. P. GILLETTE, Experiment Station, Ft Collins, Colo.

MR. S. W. HALL, of Wyoming, has been offering Editor Hutchinson, of the Bee-Keepers' Review, some suggestions. One of them is referred to in the following paragraph:

"Boil it Down," is what Mr. S. W. Hall, of Wyoming, would be pleased to have us editors and correspondents do. He says that he takes the bee-journals to get new ideas, but he is obliged to scratch over so much chaff for a few grains of common-sense that he is sometimes tempted to forego the reading of all of the journals until they learn to boil it down. Long articles are sometimes necessary and valuable; but, if I understand the spirit of Mr. Hall's criticism, it is not to these that he objects, so much as to giving space to articles that are of little or no help to real, practical honey-producers.

Mr. Hall should read the American Bee Journal. If too busy to do that he is likely too busy to waste his time keeping bees. He reminds us of many a beginner in bee-keeping who thinks he can't afford to spend one dollar for a good bee-book and another dollar for a good bee-paper. A man who can't afford to start right in any business especially when

it costs so little, can't afford to start in it at all. And yet, such a man usually thinks he can afford to waste his neighbor bee-keeper's time by asking a hundred questions that are answered by the book and paper.

Of course, in a measure, Mr. Hall is correct, and for that reason we have our department of "Beesdom Boiled Down," so that bee-keepers really need read only the American Bee Journal, and thus save time and money, and also get practically all the latest and best ideas on the subject of bee-keeping.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., JULY 25, 1901.

No. 30.

✻ Editorial. ✻

One of a Thousand.—Are you one of a thousand members that the National Bee-Keepers' Association ought to have before the convention to be held in Buffalo, in September? Last week we reported the names of four persons who had sent us their membership dues. This week we record the following:

JOHN BALUSS.

JOHN S. DOWDY.

New names will have to be sent in more rapidly than during the past two weeks if we are going to secure the necessary 200 among the readers of the American Bee Journal. That was what we thought could easily be done. And it can be—if only 200 among all the thousands who are not yet members of the Association would simply send in the one dollar each.

Of course, it is not necessary to send your dollars to us—send them direct to General Manager Eugene Secor, Forest City, Iowa, if you prefer. But we can publish the names of only those who send to us. We will then forward the money to Mr. Secor.

Now, can't we have a long list of new names next week?

Grading Honey.—Mr. D. W. Working has an article on this very important subject in this number of the American Bee Journal. Every bee-keeper ought to read it, and then heed it. We have handled enough honey to know that most bee-keepers know very little about the grading business. Of course, each knows that no other bee-keeper ever produced as fine honey in every way as his! And no one grades as honestly as does he! It's always the "other fellow" who puts the finest and whitest sections of honey in the front row, next to the glass, and then fills in back of him with "any old thing!"

One needs only to see the promiscuous lots of honey that are received by a honey-dealer, to be convinced that on the subject of grading there is much to be learned by most bee-keepers. And uniformity of grading—well, you might almost as well talk of controlling breeding so that all calves or colts will be of the same size and color!

But it will pay to continue to call attention to this subject that really does mean so much to honey-producers.

Read Mr. Working's article, and then see if you can't hereafter do better work along the line of grading honey.

Bees Superseding Queens.—G. M. Doolittle says in the American Bee-Keeper that fully three-fourths of his queens superseded by the bees are so superseded during the three weeks immediately following the maiden flow. So any queen that he wishes to replace at that time is disposed of, and a ripe cell given a day later, unless a cell-protector is used, in which case the cell is given at the time of removing the queen. A plan not generally known he further gives:

Another plan which I have often used since my apiary became very much improved beyond what it formerly was, is to rear a lot of cells from my best queen at the time given above, and 24 to 48 hours before they are booked to mature, give one to each colony having a queen more than one year old, using a cell-protector for each one, and placing this protected cell in one of the sections on the hive, or anywhere I best can where the bees can cluster about it, without hunting out the old queen at all; when, if the bees have any notion to supersede their queen, they will accept of this young one and destroy the old queen. If they destroy the young queen, I allow the old one to remain, thinking that the bees know what is right, and in 19 cases out of 20 where the bees decide on keeping the old queen, I find she proves *par excellence* till after the honey-flow of the next year is over. This is something which does not cost much labor, and which I practice often to my satisfaction.

In-Breeding is generally supposed to be a thing that should in all cases be avoided, and bringing evil and only evil in its train. Those who are well-informed tell us that some of the best results in breeding have been obtained through the very closest breeding, and this has been emphasized so strongly that some might be led to think that no care whatever is needed to avoid in-breeding. A very wide gulf lies between the two teachings. On one side lies the teaching: in-breeding must never be allowed. On the other side lies the teaching: pains must be taken to practice in-breeding if the best results are to be obtained. The truth in such cases is generally to be found in middle ground. In this case the middle ground would be very welcome to the lazy breeder, who would interpret it as being: take no pains to avoid in-breeding, and take no pains to practice it, but let nature take its own course. In this case, certainly the middle ground so interpreted is not a safe ground.

We are told that in-breeding is not a bad thing *per se*. Perhaps. How can in-breeding be a bad thing when such grand results have been obtained through its practice? But were the results obtained because of in-breeding or in spite of it? Darwin says there is no mysterious evil in the mere fact of the nearest relatives breeding together, but the evil follows from the circumstances of near relatives generally possessing a closely similar consti-

tution, and that however the fact be explained it seems a fact that for the most vigorous progeny there must be a certain differentiation between sire and dam. That sounds like saying there is no evil in in-breeding *per se*, but it comes perilously near it if attendant circumstances are so commonly such that evil results. It would be unwise to dogmatize with none too much knowledge on the subject, but there may be no harm in asking a few questions:

Did those breeders who obtained such good results from in-breeding breed from near relatives because they were near relatives, or because they possessed, in common, qualities desired to be perpetuated? Would a father ever have been bred to a daughter as sire and dam if another than the father could have been obtained possessing the same qualities as the father without at the same time being nearly related to the daughter? Is it not the safe thing for those who do not take great and special care, that they shall take all the pains possible to avoid in-breeding? Is it not well that more should be known about the laws of breeding, so that a goodly number of the craft could be engaged in an intelligent attempt to improve our bees?

The Saw Palmetto is an important honey-plant. That same remark about white clover would perhaps elicit a smile of pity, for every one is supposed to know white clover honey, yet saw palmetto is to the Florida bee-keeper, the editor of the American Bee-Keeper says, what white clover is to the Northern producer of honey. "Hundreds of thousands of acres of Florida sand are covered with a scrub growth of it, while in moist and richer localities it grows in impenetrable jungles, and is one of the most beautiful of our sub-tropical palms," so says Mr. Hill.

In the same journal, W. S. Hart says it is a tree whose trunk may lie under the surface of the ground or upon it, or it may rise 10 or 12 feet high in the air. It is one of the cheapest and best sources of tannic acid for tanning leather. The pinnated leaf is used to make paper, especially of finest quality, and capable of holding oil and other liquids. It also makes a very clean and springy filling for mattresses. The bloom is composed of small cream-colored flowers on racemes from one to three feet long, and the honey is of a fine light-amber color, heavy in weight, and of good flavor. Another grade of honey is obtained by the bees from the juice which oozes through the skin of the berries, which are from the size of an olive to twice that, and seem to be a wholesome food for hogs, cattle, bears, and people.

Contributed Articles.

Grading Honey—Its Importance, Rules, Etc.

BY D. W. WORKING.

Secretary of the Colorado State Bee-Keepers' Association.

THE bee-keeper is a partner in a co-operative business; he furnishes the hive and its accessories and markets the honey and wax which the bees produce. But he does more. Between the work of preparing the hive for the bees, and marketing the product of their labor, the bee-master has other work to do. He is more than a partner in a co-operative establishment—he is both manager and joint worker, and on the wisdom and skill with which he works and manages depend in a large measure the success of the business venture.

The bee produces the honey. But will it make straight combs, even, white, and well-capped, if hive and sections are not properly prepared for its use, and if they are not properly cared for during that use? And if all the preliminary work is well done, will the product be ready for an exacting market without additional work and care? The fruit-grower picks his berries and his apples when they are in the best condition for the trade; he sorts them carefully and puts them up in attractive packages in order to command the best prices the market affords. Skill in raising, experience in handling, wisdom and foresight in catering to a varying demand—these are the secret of his success.

The bee-keeper must do more than to induce his bees to put their product into clean sections; he must keep the sections clean and unbroken; he must meet the demands of the trade. To do this he must take the honey from the hive at the right time, must make each section as clean and inviting as possible, and then assemble the sections properly in attractive packages. People like what is good, and like it better if it looks good. What is clean suits them better if it looks clean. A stain on the outside of a section does not make the honey less sweet or less wholesome, but does make it less attractive to the buyer. The stain, therefore, must be removed before the section is offered for sale.

Uniformity counts; therefore the bee-keeper must make his packages uniform—in size, in shape, in color, in arrangement. A few leaking sections are too many; a single badly graded case may spoil the sale of a ton of honey. So the individual must be careful in grading, in handling, in packing, and in selling his products. But this is not enough. The market is too big for one man to supply. Honey is bought and sold by the car-load—even by the train-load—and the buyer is wise enough to insist on uniformity of grading in the whole lot. The packages must be uniform or he will complain; the packing must be uniform or he will find fault; the honey itself must be uniform or he will not pay the highest price for it. He is a kicker—the buyer is—and he ought to be! So the uniformity of grading and packing which is necessary to the individual is necessary to all who help supply the market.

The Colorado State Bee-Keepers' Association has undertaken to provide a system of grading rules that will make Colorado honey as famous for evenness and honesty of classification as it is for quality. It is hoped and intended that "No. 1 Colorado Honey" shall have a meaning as definite and precise as any other trade name may boast. To this end, every member of the Association is furnished a copy of the rules and recommendations, and urged to follow them as faithfully as if he were to be paid liberally for doing so in addition to winning an honorable name for himself and his State. Indeed, the man who follows the rules carefully and wisely will be paid for his faithfulness in the higher price he is sure to get for his products.

The rules are not supposed to be perfect; but they are believed to be better than those of last year. I may venture myself, to add a suggestion: In case of doubt in classifying, give the lower grade the benefit.

The rules and recommendations of the Colorado State Bee-Keepers' Association are as follows:

COMB-HONEY RULES.

No. 1.—Sections to be well filled and capped, honey white or slightly amber, comb white and not protruding beyond the wood, wood to be well cleaned; cases of separated honey to AVERAGE 21 pounds net per case of 24 sections, with a minimum weight of not less than 20 pounds for any single case; cases of half-separated honey to AVERAGE not less than 21½ pounds net per case of 24 sections, with a minimum weight of 20½ pounds for any single case; cases of unseparated honey to AVERAGE not less than 22½ pounds net per case of 24 sections, with a minimum weight of 21½ pounds for any single case.

No. 2.—Includes all amber honey of a pronounced tinge, and all white and amber honey not included in No. 1, to be fairly well sealed, uncapped cells not to exceed fifty in number exclusive of the outside row, wood to be well cleaned; cases of separated honey to AVERAGE not less than 18 pounds net per case of 24 sections.

EXTRACTED-HONEY RULES.

Extracted honey shall be classified as white and amber, shall weigh 12 pounds per gallon, shall be perfectly free from particles of wax, and shall always be marketed in new cans. All rendered honey, whether obtained by solar heat or otherwise, shall be classed as "strained" honey and not as "extracted."

RECOMMENDATIONS.

It is recommended to sell all cull honey around home as much as possible; to grade only in daylight, near a window; to use the standard 4¼x4¼x1½ inch section and the 24-pound double-tier shipping case, in order to have uniformity in loading cars; to stamp all cases of No. 1 honey with the owner's name above the handholes; to mark all cases of No. 2 honey with two dashes in the handholes at each end of the case, and with no other marks whatsoever; to use no second-hand cases for No. 1 and No. 2 honey; to pack all sections with paper below and above, and in double-tier cases to put a sheet of paper between the tiers; to store comb honey in a warm, dry place, protected from flies and dust; and to handle carefully, well protected from dust and rain.

Do Bees Spread Pear-Blight?—The California Bee and Fruit Case.

BY E. R. ROOT.

TROUBLE has been brewing for some months between the fruit-men on one side and the bee-men on the other at Hanford, in the San Joaquin Valley, Calif. On the part of the first-named, the contention was that the bees, the property of the other parties, were the principal means of spreading the pear-blight, which had been working such awful havoc among the pear orchards in the vicinity mentioned. The bee-men, on the other hand, took the ground that their stock were not carrying the pear-blight; and, even assuming that they might do so, averred that other insects, and birds, as well as the wind, might and could do all the mischief laid to the door of the bees, and that, therefore, the removal of the insects under the direct control of man would not afford the relief sought. The contention waxed warm. Each side called special meetings to discuss the matter. Bitter words as well as threats were used. Some of the more rabid of the fruit-men proposed

No. 1 HONEY.

No. 2 HONEY.

to use poison to exterminate the bees in case they were not speedily removed by their owners. This only tended to aggravate matters. The bee-men retorted that, if any one were foolish enough to resort to such a procedure, not only killing the bees but endangering the lives of human beings, they would meet them on the issue half way; that they had, as backing, the National Bee-Keepers' Association, which had hundreds of dollars to its credit, had fought many cases in court, and had always been successful; that, moreover, it had decisions already on the question of poisoning bees, and that the fruit-men "could drive ahead" if they wished to. The latter maintained that they "had looked up the law," and that they knew what they were about.

It appears that those who indulged the most freely in this war of words were not those who had the largest interests at stake, either in the bees or in the pears; that the large pear-growers as well as the largest bee-keepers were men who indulged in no threats, but who believed that a compromise might be effected between neighbors who were men of fairness as well as men who are willing to listen to reason, and so the sequel proved.

The president of the National Bee-Keepers' Association was asked by resident members to make a visit to the scene of the impending trouble; investigate, and take such action as might, after a conference, seem most advisable. Accordingly, on the 18th of June, that officer appeared at Hanford, Calif., being dropped, as it were, into that "nest of hornets" by the redoubtable John H. Martin (Rambler), and J. C. McCubbin, who came with him officially and unofficially to see that no harm was done him; but, be it said, they deemed it advisable to go home that same day, although they did participate in one or two little "skirmishes" on the street. Unfortunately the Rambler didn't have along his invincible umbrella and stove-pipe hat; for with such offensive and defensive weapons he would surely have come off victorious. As it was, it was a "draw" and he departed with John C. under his arm.

It appears that the local members of the Association had made a great handle of the coming of the president of the National; of the strength of our organization, how it had never lost a case in court, and that it had secured valuable decisions from the high courts. But as he did not come at the time expected, and days went by, and still he did not come, the fruit-men began to think that this talk was all "bluff," and when he did appear, there seemed to be a feeling on their part that he had come, not to bring peace, but war, and that an organization that would send a "walking delegate" clear from Ohio surely meant business. After a little sparring on both sides, a truce and a compromise began to be talked of. On our side was a special committee appointed by the Central California Bee-Keepers' Association, at its last meeting, to meet the representative of the National Bee-Keepers' Association; and on the other was N. W. Matheral, Horticultural Commissioner, of Hanford, Calif., who seemed to represent the fruit-men, but who some jokingly said was the mother of the whole trouble.

When both sides got together it was suggested by one

of the fruit-men that, as a compromise, the bees be moved from the vicinity of the pear-trees during the time they were in bloom, and that, after they were out of bloom, and when the alfalfa began to yield nectar, they be returned to take the heavy or main crop. This, it was thought, would give the bee men time to investigate for themselves, and if, after investigation, it was shown that the claims of the fruit-men were well-grounded, afford in the meantime the necessary relief. This was finally agreed to, although it would entail a big expense on the bee-men.

It may be wondered why the latter were willing to listen to a compromise at all. In the first place, they desired to be fair; and, in the second place, the fruit-men had the testimony of Prof. M. B. Waite, Assistant Chief of the Division of Vegetable Physiology and Pathology at Washington, D. C. This official takes the position that bees do carry the microbes of pear-blight from flower to flower while the trees are in bloom. In this opinion he appears to be supported by Prof. N. B. Pierce, Pathologist of the Pacific Coast Laboratory, Santa Ana, Cal.

The following letter, directed to N. W. Matheral, Commissioner of Horticulture at Hanford, Calif., from Prof. Pierce, explains the position of the scientists, in a nutshell:

Mr. N. W. Matheral, Horticultural Commissioner, Hanford, Calif.—

Dear Sir:—In fulfillment of my former letter, and in reply to your request, I herewith give the main facts upon which are based the claim that bees take an active part in spreading the disease of trees variously known as pear-blight, twig-blight, fire-blight, etc.

1. Pear-blight is a bacterial disease which affects pear, apple, crab-apple, quince, and related trees. It is induced through the action of a specific micro-organism belonging to the bacteria, and known as *Bacillus angulivorus* (Burrill), de Toni.

These facts have been demonstrated by many scientific workers by careful inoculation, experiments conducted with pure cultures of the bacillus. The cause of the disease has therefore been well known for many years.

2. The identity of the blight of pear-trees in the Clow and Taylor orchards near Hanford (these particular orchards are cited only for the sake of accuracy, as there are many others affected) with true eastern pear-blight has been demonstrated at this laboratory. *Bacillus angulivorus* was isolated in pure culture by the plate process from blighted branches from Mr. Clow's trees, and a young and thrifty pear-tree was inoculated, and died to within a few inches of the ground of the true pear-blight. A control tree treated the same way as the inoculated tree, except that the bacillus was not introduced, remained perfectly healthy.

Mr. M. B. Waite, Assistant Chief of this Division of the Department, has kindly supplied the following additional facts bearing on this matter:

3. "The occurrence of the blight on the blossoms in great quantities, and the great rapidity with which the disease spreads from flower to flower, indicates a normal and very effective method of distribution."

4. "The germs were found growing freely in the nectar of the blossoms."

5. "Bees were seen repeatedly visiting the infected flowers, and some were caught taking infected nectar, and, by means of plate cultures, the pear-blight germs were isolated from their mouth parts."

6. "By covering parts of the trees with sacks of various kinds of material, and then artificially infecting certain flowers on the tree, the blight was observed to spread very freely over the uninfected and uncovered blossoms, but was entirely absent in the blossoms covered by mosquito-netting."

7. "Blossoms were infected, and at once covered with sacks, and the blight, in such cases, was retained in the infected blossoms."

8. "Pear-blight germs died very soon after being dried up, and lived for only a brief period on exposure to weather conditions out of doors, hence they can not live in dust, and be blown around to any great extent by the wind."

9. "Pear-blight virus, particularly that which occurs on blossoms, is a very sticky substance, and is readily carried, by insects, birds, or other animals, but cannot be blown in the wind."

This brief presentation will, I believe, furnish your board with the main facts needed to show the connection existing between the visits of bees to pear-flowers and the spread of pear-blight.

Sincerely yours, NEWTON B. PIERCE.

April 23, 1901.

Pathologist in Charge.

Prof. Pierce happened to be in the city at the time, and in an interview which we had with him he gave utterance to substantially the statements as are given above. If anything, his verbal statement incriminating the bees was even stronger. So far as I could judge, he seemed to be a competent scientist, and a fair-minded gentleman; but, unconsciously, he is, prejudiced, I think, in favor of the pear-men, with whom he has some much in contact of late.

I asked him if it were not true that wild bees, insects and birds, over which man has no control, could do all the mischief ascribed to the bees. He admitted that this was possible, but not probable. Did he not think that bees were valuable as fertilizers of the blossoms, especially of those of the Bartlett pear? He thought they were. Well, did not this service of the bee, year in and year out, more than counterbalance the alleged mischief done by them in the occasional year when pear-blight was so prevalent? He could not say, although he was of the opinion that, by a certain alternation of varieties, the services of the bee might be dispensed with entirely; but of this he was not sure.

From Prof. Waite's statements it would appear (to express it in common parlance) that the bees have been caught "red-handed," bearing the marks of the alleged criminal act. If I understood Prof. Pierce, he had not found the bacteria of pear-blight on the tongues of the bees, nor had he himself seen the microbes in the nectar. If this be true, we have, as the only real incriminating chain of evidence, the statement of Prof. Waite. Without detracting in the least from the skill of the professor, it is proper to remark that even the best of scientific men make mistakes, and we, as bee-keepers can not accept the unsupported statement of Prof. Waite without further investigation by some of our men equally competent and fair.

This is a nice question, as a lawyer would say, and we need to go at it carefully and candidly to get at the truth, cut where it may.

There is some evidence that goes to show that Prof. Waite is mistaken. For instance, there are young pear-trees, acres and acres of them, that have never been in bloom, and yet these young trees are blighted to death. How in the name of reason did the bees carry blight to these trees when it is apparent that they never went near them? And then there are little shoots that have pushed up from the ground since the big trees were in flower, and yet these shoots are blighted like the rest. Assuming, for argument's sake, that bees may carry the blight on old trees, we must admit that there is some agency, possibly the wind, Prof. Waite to the contrary, that carries the destructive microbe to the young shoots and the young trees. There are some things that are not explained yet.

Again, I believe we have the right to insist, for the present, until we have more corroborative evidence, that wild bees, other insects, and birds, over which man has no control, may be able to spread the blight just as much as the bees under the control of man. For example, this illustration was used: If a barrel full of water has two plugs in it near the bottom, the larger plug, represented by the tame bees, and the other plug (the small one) by insects, birds, and wild bees, will not the small plug exhaust the barrel just as surely as the large one? If this be true the removal of the bees controlled by man would not bring the relief expected, by a long way.

In conclusion, let me say that I visited the worst-affected large pear-orchards in the vicinity of Hanford, Calif. The large pear-growers were fair, intelligent men. While they thought the bees were to blame, they also thought the pear-men had some responsibility in the matter.

I visited one orchard of 120 acres, and every tree was badly blighted, and no mistake; but in this orchard we found the badly-blighted little shoots I have referred to.—Cleanings in Bee-Culture.

California for Bees—Motherwort, Etc.

BY PROF. A. J. COOK.

PROF. C. P. GILLETTE, of Colorado, desires me to give the comparative merits of the different parts of California for bees. The southern portion of the State would be incomparably superior were it not for the too frequent drouths. When we have good years the crop is immense, and the honey—mostly sage—is very superior in color and flavor. But the dry seasons are too common. In the 7 years since I came here there have been but 3 excellent seasons, while two of the seasons were complete failures. It is possible that at some time in the future we may be prepared to water large sage areas, in winter, when there is too little rain, and when water can be had cheaply, and so remove this uncertainty. In such case Southern California would lead the world.

Central California the great San Joaquin Valley—is becoming very noted as a locality for bees. The extensive

fields of alfalfa in Fresno, Tulare and Kings Counties, make the honey crop almost certain; and the quality of the alfalfa honey leaves nothing to be desired.

In Northern California there are always abundant rains, and in some sections, as along the Sacramento river, there are extensive areas of alfalfa. If the North had as fine honey-plants and in as rich profusion as the South, then Northern California would be at the head for honey-production.

Prof. Gillette asks especially about Sonoma County. If one is sure of honey-plants he may have no fear. It would be wise, if possible, to locate close by a large acreage of alfalfa, as then failure would be almost sure of elimination. There must be generous watering in winter to insure nectar-secretion. The owners of alfalfa will look to the watering, and so the honey crop will be assured.

MOTHERWORT AS A HONEY-PLANT.

Mr. Arthur A. Houser, of McDonough Co., Ill., sends a nice sample of this plant, of which he writes:

"I send you a flower which grows abundantly here. I haven't been able to find a botanist that can give me its name. Will you please name it through the American Bee Journal? The bees are on it from early morning till late at night. I feel sure it must be a very rich honey-plant. Do you not think I would better encourage its growth here, as it flourishes well with half a chance?"

This is one of the best mints of the East. It is the common motherwort—*Leonurus cardiaca*. It is illustrated in my "Bee-Keeper's Guide," page 357, where I fully explain its excellence as a honey-plant. It is one of the mints, and so has excellent relatives in the horse-mint and white and ball sages. It belongs to the family Labiate, so named from the two-lipped or bi-labiate form of the flowers. Such irregular flowers have developed, as we are assured, that bees, etc., might the better cross-pollinate the flowers. Other families with irregular flowers are familiar in the Scrophulariaceae and the Legumes. In the first is the excellent honey-plant—figwort—and in the latter all the clovers. The irregular flowers are so formed that the bee, as it reaches in to get the nectar, is sure to become dusted with the pollen, which, as the bee flies away, will be borne to the stigma of the next flower visited. The very fact of irregular flowers tells that we have honey-plants.

CORRECT USE OF NAMES.

I doubt if we can be too careful in using names correctly. I have a theory that to use terms loosely tends to beget untruth, and, conversely, to use words precisely works to make one more truthful. This, and to be more correct in our language, is surely enough to influence us all. Thus I would urge all to help to correct some very common faults of expression. I say faults, though the dictionaries may permit some of them. Our dictionary makers are conservative, and follow rather than lead in nice distinctions. The best way to gain the latest and best is to study the works of specialists. They must be accurate and precise.

The entomologist would never call a larva a worm. Insects are a branch separate from worms, and are very different in every way. A worm—an angle-worm is an example—is always the same in form and appearance. Thus a worm just hatched from the egg is like the mature worm, except it is small. Worms have no feet, nor any specialized organs for breathing. We may rightly say angle-worm, sea-worm, tape-worm, round-worm, etc.

The larva of insects are different. They are very unlike their matured selves—usually have feet—have respiratory organs. If these are to develop into butterflies or moths, we call them caterpillars. These always have from 10 to 16 legs, usually the latter number. If they are to develop into two-winged flies, like house-flies, we call them maggots. These are footless. If they are to become beetles, we call them grubs, when they usually have 6 legs, though some, like the grubs of weevils, are also apodous or footless. Another mistake is to call insects bugs. Only one order of insects are bugs. We may say chinch-bug correctly, but to call a beetle or locust a bug is as much an error as to call a rat a hippopotamus. Let us do all we can to secure more accuracy in the use of such names.

Los Angeles Co., Calif.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

No. 9.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

I BELIEVE it is safe to assert, Mr. Bond, that in all the intelligent universe, so far as our knowledge extends, there is not a creature so low in the scale of intelligence that it does not in some degree appreciate human kindness, gentleness, sympathy—all expressed in the word *love*. Of course, it is easy to deny this statement; but it is by no means easy to prove it false, in theory and manifestation. Only a moment's reflection brings before your mind the fact that it requires but little effort on your part to make your horse, your dog, or even one of your hogs, love you—as far as an animal is capable of manifesting that quality of intelligence."

"But I came to the conclusion a few years ago that we have no safe guide by which to draw the line of limitation, in the scale of intelligence downward, beyond which we find no evidence to support my statement, when I read in a journal of science of a man in England who had trained quite a number of *fleas*!—to such an extent that he could hitch them to a cart purposely made for them, and to draw it, as horses do a wagon. And several other things he had taught those little creatures to do—all by the constant and persistent exercise of tact, patience and kindness toward them.

"I don't pretend to know how a flea can appreciate human kindness—I am only speaking of the fact as reported. I am convinced, however, mainly by personal observation since I began to handle bees, that in some mysterious way they can and do appreciate kind treatment. In the same way I have also learned that they have a keen appreciation or comprehension, of the other kind of treatment; and you know as well as I do how promptly and effectively they resent it.

"Looking at the matter, therefore, from the point of view here indicated, Mr. Bond, it is surely not a waste of time on my part to make the explanation of this principle a feature of our lesson.

"Several times, on various occasions, visiting friends have asked me, when they saw me at work among my bees, how I could do it all without getting stung to death. My answer nearly always is, *Because my bees know me*. They seem to know my touch. Possibly they also know my voice. Certainly they know me by their keen sense of smell.

"Mark that last statement well, Mr. Bond." I continued, looking sharply into his eyes through the meshes of his bee-veil as I spoke. "It is of greater importance than you may think; not because it is a controverted proposition among the most intelligent class of bee-keepers, but because as a positive statement between you and me, it implies that I mean it, that I believe it because I have been convinced of its correctness by evidence that satisfied my reason.

"Yes, Mr. Bond." I continued, impressively, "it is one of the articles of my bee-keeper's creed, that *Bees have a keen sense of smell*, and I'm not ashamed of it—neither am I fanatical enough to be ready to fight for it. And—let me tell you this in strict confidence, Mr. Bond—whenever I hear of an intelligent, well-educated man who, as a professed bee-keeper, denies, point-blank and on foot, that article of my creed, I intuitively suspect him of all, or at least some, of such unprofessional habits as the smoking and chewing of tobacco, drinking of whiskey, and eating of garlic and limburger cheese.

"I know very well that it sounds like a silly paradox to make a statement of that sort." I hastily commented, when I saw through his veil a plainly outlined expression of ironical incredulity upon his otherwise jovial face. "Because, the thought naturally suggests itself that the best trained and most loving bees in the world would be sure to go for such a man, hot-end foremost, if he ventured within bee-smelling distance. I say, the proposition naturally assumes a paradoxical look of that sort. But the paradox is at once seen to be a delusion, in a practical sense, when I explain that it is *because* of that fact of the bees refusing to own him as a friend, that a bee-keeper thus guilty of offending their olfactory nerves persists in denying that the sense of smell is an inherent part of bee-nature. *They do go for him*.

"I fear I have wasted time in an effort to make you see the point of my argument, which I can so plainly see and feel. But, nevertheless, I trust that my effort to handle a

delicate subject through the texture of the proverbial 'kid gloves' is not wholly lost."

This conciliatory comment was offered because I knew that my friend and pupil was guilty of the tobacco habit; though not of the other two.

"Beg your pardon for this digression, Mr. Bond, and for keeping you waiting to proceed with the drone-lesson. If you'll now examine the smoker to see that it is in working order, we will finish taking off that super. Of course, you remember my caution not to lift before you are sure you have a secure hold at both ends, and to be careful not to crush any bees when you set the super down."

Following my directions, Mr. Bond lifted one end of the super high enough above the frames so that he could blow a little smoke underneath it among the bees, to prevent them from making a demonstration when the super was finally lifted clear of the hive.

"This as a precaution," I explained. "It is better to do that, though it's a little more trouble because you must handle the smoker and one end of the super at the same time. You see, if you lift the super suddenly, the bees underneath are startled, not knowing what is going to happen, and, as a rule, they make a rush. The result is that often, before you can properly take care of the heavy super—supposing it to be full of honey—and get back to the hive, thousands of the bees are flying just where you want to take your stand to do the work you came there to do. To say the least, it may cause some unnecessary annoyance to have it that way. But there are times and circumstances when something very much worse than annoyance may be the result. As, for instance: the entire colony may become alarmed and assume a belligerent attitude, especially when you are handling old bees, and at a time when there is only a light honey-flow. Or, the colonies nearest the hive you are working at may be aroused by the alarm-signal given by the flying bees. In that case they will first mingle with those in the air to investigate the cause of the commotion; but, almost invariably in such an instance, these neighbor-meddlers will next proceed to investigate the open hive, with the result, well-known to all practical bee-keepers, that you have a case of robbing on your hands when you were least expecting it.

"I am telling you all this at this time, Mr. Bond, in order that you may be on your guard for such emergencies whenever in the future you have a job like this to do. 'An ounce of prevention is worth a pound of cure,' applies here, Mr. Bond, in the sense that a little precaution, with a little smoke judiciously applied, will often prevent—well, it's hard telling what not. Every experienced bee-keeper will endorse that, I think.

"Now for the drones," I said, after Mr. Bond had deposited the super, without crushing bees or getting stings on his hands, and had returned to my side near the hive.

"Please take this prying instrument"—handing him my old chisel—"and show me how nicely, carefully and gently you can loosen the ends of those brood-frames with it without alarming the bees. They are all glued fast, more or less securely, hence you must avoid sudden snaps and jerks."

Mr. Bond took the chisel and bravely began the job. He was getting along very well until he reached the last frame. The bees had done a little more work on that, seemingly, than elsewhere, and as a consequence my friend had a little more trouble with it, and was obliged to use a little more force to loosen it. Quite suddenly—as such mishaps, especially in the apiary, always do happen—his chisel slipped and down went the frame with a bang. Before I had time to use the smoker, or he to realize what had happened, about a score of bees made a dive at his naked hands. Fortunately, I had told him the day before that when ever bees did that, to keep his hands perfectly still for a moment and not to jerk them back; for if he did that they would surely sting. This he now remembered and put into practice, with the result that, though most of the assaulting bees went through the manoeuvre of stinging, not one of them made earnest of it.

"Good! good!" I shouted approvingly. "Now you are initiated, Mr. Bond. That kind of an experience is to a bee-keeper recruit what the first charge in the first battle is to an army recruit. I think you can stand fire now, Mr. Bond, when you and any man's bees get into a fracas.

"Go ahead now and lift those frames out for inspection. You can do it as well as I can. Begin with the one you have just loosened and hand it to me; I want to see whether there is any drone-brood on it or not."

To be continued.

* Biographical. *

MR. ROBERT WILKIN.

We present on the first page this week the latest picture of one of the leading pioneer bee-keepers of California—R. Wilkin. His son-in-law, Mr. J. F. McIntyre, has kindly sent us the following biographical sketch:

Robert Wilkin was born near Londonderry, Guernsey Co., Ohio, July 4, 1829, and died at Newhall, Calif., May 30, 1901. He leaves two daughters, Mrs. J. F. McIntyre and Mrs. J. M. Owens, and 8 grandchildren.

He was educated at Westminster College, New Wilmington, Pa. Soon after leaving college he married Eliza Williamson, who had attended the college at the same time. He had one daughter, Harriet, by this marriage, his wife dying when the child was 9 months old. About 4 years later he married Isabella Gordon, by whom he had one daughter, Mary. His second wife died in 1888.

Mr. Wilkin made a specialty of the bee-business for nearly 40 years; he left a journal of the business from 1862 to 1901, in which I find many interesting items. His first investment in this line was to buy the patent-right to make and sell the Langstroth hive in several counties in Ohio. This venture was not a financial success. The next venture was to buy up a lot of black bees, transfer and Italianize them, and commenced the business of selling Italian queens, and colonies, at Cadiz, Ohio.

I find among the first items that he paid L. L. Langstroth \$25 for an imported Italian queen, and sold 20 colonies of Italian bees at \$20 each. An item in November, 1871, says: "I have 300 nuclei, and have sold this year over 800 Italian queens at \$6 each. Nov. 5, 1872: I reared this season 2,000 queens; 400 of these were sold at \$250 per hundred, and the balance at \$5 to \$6 each; and bought of A. Grimm 72 colonies of pure Italian bees at \$11 each."

This was too good to last, for on May 15, 1873, he writes: "Of my 315 hives of bees in the fall, only 61 are alive now." June 5, 1873, bought of Dr. J. J. Adair, 85 colonies of bees at \$6 each." He continued to lose his bees in winter and buy more in the spring to carry on queen-rearing, until the spring of 1874, when he moved all of his bees and family to Oskaloosa, Iowa, to try producing basswood honey. After two seasons of failure and loss of bees here he moved all of the bees he had left—240 colonies—and his family, to San Buenaventura, Calif., arriving Nov. 6, 1875.

In 1871 he wrote a book of 96 pages, entitled, "Hand-Book of Bee-Culture," price, 25 cents. But he gave away more than he sold, to save himself the trouble of answering so many questions while selling queens. The book is now out of print.

After coming to California he turned his attention entirely to the production of extracted honey. California honey had not made its reputation at this time, and it was hard to dispose of large crops, and on Nov. 1, 1878, he left his bees in charge of E. Gallup, while he went to England to sell his crop of 45,000 pounds of extracted honey. Subsequently he made trips to Boston and Texas to sell honey. His largest crop was 100,000 pounds from 1,000 colonies in 3 apiaries in 1884. He retained his interest and enthusiasm in bees to the time of his death, and was actively engaged in living swarms when he was taken with cholera morbus, and after 12 days' sickness died on May 30, at the age of 71 years and 11 months.

Mr. Wilkin was president of the California State Bee-Keepers' Association during the last two years. His hobby was co-operation. He was always willing to lend a helping hand in a good cause, and served his country during the Civil War in the 42d Ohio Volunteer Infantry.

J. F. MCINTYRE.

One by one the bee-keeping pioneers are passing away. Soon there will be none left to give personal reminiscences of the days of Langstroth, and Quinby, and Wagner.

California has perhaps in the line of extensive apiaries, Mr. J. S. Harbison (still living, we believe) leading at one time with his 6,000 colonies of bees—the largest bee-keeper in all the world. Next to him likely came Mr. Wilkin, at least in the size of his honey crops, as mentioned by Mr. McIntyre.

But what of the future of bee-keeping? Will there arise worthy successors of the noble ones who have lived, labored, and then passed on? Yes, we believe there will be. Already a new interest is being taken in bees and the production of honey in many localities. The bee-keepers of the present are taking advantage of the experiences of the past, and with the progress of the present will undoubtedly surpass even the wonderful results attained by those of the years gone by.

Our pursuit is an honorable one. Indeed, "Our toil doth sweeten others." And as the years come and go, "others" will include more and more of the sweet-loving public that now know not the taste of "nectar fit for the gods"—delicious honey.

Above all things let us strive to emulate the grand examples as shown by the lives of those who have been translated to that Heavenly sphere, such as Langstroth, Quinby, Cary, Wilkin, and many more that might be named did time and space permit.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

LIVING ON HONEY ENTIRELY.

I wonder how nearly a man could come to living entirely on honey—a man not a laborer, but one whose work is mainly mental. In other words, I wonder how much of a lie that is on page 365 where it says Pythagoras lived only on honey. I have hung up in my den a funny picture entitled, "George Washington trying to tell a lie." May it not have been that this was the one he was trying to tell?

A QUEER KIND OF ORNAMENT.

We've seen many sorts of things to ornament apiaries, but never strings of decapitated human heads before. Ask Mr. Haun if his State has "done gone" and annexed itself to Borneo. Frontispiece No. 24.

COUNTING BEES BEFORE THEY'RE HATCHED.

My parents came to Ohio in 1843. Suppose I should reason on how many Hastsys of the stock there ought to be here, instead of saying how many there are. When a chap starts in to count a colony of bees by saying, "The queen has laid so many eggs per day for so many days;" then's the time to hustle him toward the door—just a little, you know. Counting bees before they are hatched is not better mathematics than counting chickens before they are hatched, but decidedly the reverse. Amount of inside surface in the hive, and general number of bees to the square inch, will yield a better approximation than egg-counting can do. Yes, we'd like to know who's got the most numerous straight colony; and it's sadly awkward that weighing bees is so much trouble except at swarming-time. Page 371.

A HOMELESS QUEEN.

I would say to Mr. Crafton, page 381, that it isn't very common for queens to be "lighting down upon us at our work. As for one way it might have happened, perchance a colony had been superseding its queen, and as usual reared several of them. Two chanced to emerge about the same time, one was accepted; and the other (the bees not wishing to swarm) was driven out of the hive. Finding herself homeless she prospected the open hive you were at work at to see what it might offer in the way of a home.

BEES AND GROCERIES.

Dr. Mary McCoy writes up an exceptional location in an entertaining way on page 387. Abundant pasturage on two first-class honey-plants, and scarcely anything else. One could well afford to do some feeding in spring if tolerably sure of a mid-summer and fall with fair honey-flow of white honey. It looks as if grocers as well as other men are reasoning creatures. Unusual quantities of bees shipped with the fruit, when a masked apiary close by begins to need shipping. In a small city, where the number of dealers having exposed

sweets is small, something is possible in the way of posting each one as to the habits of bees. Tell them sweets in a store will be as sacred as sweets in a home pantry if you "shoo" the first ones away and don't let them get begun. Tell them also that screening often is only needed for two or three days, until a mysterious change in weather conditions makes the flowers "give down"—after which the flowers have the preference.

QUEEN ACCEPTING THE COLONY.

I think Editor Pender is on the right track in jogging our minds concerning the fact that *the queen must accept the colony* as well as the colony accept the queen. Curiously hunger is the best peace-maker on her side, and the opposite of hunger a very necessary peace-maker on their side. Page 385.

PARTLY FILLED SECTIONS FOR BAIT.

Let's sing some more about taking partly filled sections, bees and all, to start laggards at storing honey. No experience myself (so I can slug more freely). I have wondered just a little if the wise old chaps who recommend this have figured high enough on the hindment the good colony suffers. You see, if we let a good hand spend half his day making a tramp work, and said tramp does $\frac{1}{4}$ of a day's work, we have scored a loss of 25 percent. My practice is, and my advice is strongly in the same direction, to keep bees for comb honey that don't need any such fussing. Page 387.

HINTS ON SELLING EXTRACTED HONEY.

On page 388, G. H. Pond strikes the heart of an important matter when he deprecates too large sales at one time. A lot of old candied honey well punctured with dead flies and ants—well, if an adversary wanted to keep a honey-loving family from buying any honey 800 years he couldn't contrive any better way. "Got a great lot of it on hand and can't buy till we eat it up." And it looks so repulsive they never eat it up. His experience with grocers is also interesting. Told many of them just how to relinquish—they said they would—no one ever did. "Specs that would be pretty much the same everywhere. So if a fatal drooping of sales is to be prevented at all, the man who furnishes the honey must see to it that it is kept in liquid condition."

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

NATURE STUDY.

"Flower in the crannied wall,
I pluck you out of the cranny;
I hold you here in my hand;
Little flower; and if I could but understand
What you are, root and all, and all in all,
I would know what God and man is."

Those beautiful lines from the great author, Tennyson, are rich in suggestion, and show the heart of the great poet-laureate of England. It is beautiful for us all to know the flowers, to know the birds, to be intimate with butterfly, moth and beetle. These gems of God's handiwork are intrinsically beautiful. To be on speaking terms with them, to enrich and refine the life. Peering into their wondrous secrets is ever full of sweetest and best entertainment, is ever startling us with surprises, is ever bringing us to know more of God's wondrous ways.

And how we constantly learn to see more and more as we study these wondrous fashionings right from God's own hands. Did the great poet overstate the truth when he said that to know the flower thoroughly was to know God and man? I am sure, to know the flower and insect will bring us as near God as will anything we may study, and will make us more alive with human sympathy. If, as we are often told, the country folk are more pure and true than others, may it not be that the influence of plant and flower has worked to sweeten and ennoble life?

New York, through a beautifully wholesome work of Cornell University, is bringing nature study into all the country schools, and so into all the homes. God be praised for this splendid undertaking. We may well bring it into all our home circles. Can we not get all our States to follow New York's most admirable example, and all have the leaflet, the lesson

helps, and every bid to foster this glorious nature study? Let us all urge it upon our colleges and legislatures. A little seed here will bear a most bountiful harvest.

In the meantime, let us all get the children to study flower, insect and bird. Let us with the children see just when the birds come back in spring; when and how they build their nests; how they move on the ground; how attentive and faithful the male is to his mate; how the color of the male compares in brightness with the female; which of these do the singing, and when they sing sweetest and best.

Again, let us note what insects seek and sip nectar; why wasps are about the sticky mud near well or hydrant; how the butterfly lives her wings when she alights; whether moths do the same; why the leaves of our plants are ragged; and countless other things that will be so full of interest that we shall find our days too short, and will sing with new meaning Father's beautiful hymn:

"There's a wideness in God's mercy,
Like the wideness of the sea."

THOROUGH WORK.

It was a great compliment that a young man received in my hearing from an older person, a day or two since: "I must have you at any price. You do your work so well." Do we as parents appreciate the meaning of these words—"good work?" I had a boy work for me for 3 years. He was a joy every day. He never slighted anything nor did he do one thing less perfectly because no eye was looking on. It was a great misfortune that I could not secure his help this year. He could do better elsewhere. He will constantly progress. Promotions will come thick and fast. People will fairly tumble over each other in their eagerness to secure his services. His life will be a happy one, because successful. He will always be wanted, as he will always have something most valuable to give. His work will always be speaking his praise.

Can we devote time more wisely than by use of both precept and example, to beget in our children the fixed and certain habit of doing everything well—the very best that they can? Can we use a better means than to be generous with approval? Mrs. Cook often asked me if I were not afraid of spoiling Mr. — by my words of approbation. I never saw any evil in dealing out such just praise in great, liberal, allopathic doses. In my observation, nagging, fault-finding, sarcastic jeers go very little towards making people better. I do have great faith in the use of timely and honest praise for work well done. True, we may overdo our praise of virtue, but I think we are oftentimes far too chary in awarding it.

I am sure that there are very few things that count so largely in making life a great success as the habit of doing all that comes to our hands in the very best possible way. Christ was perfection. He always did his best—and the best.

GRIT.

I have always admired the stanza from the Irishman who told how he secured so good a shillalah for use in his police duties:

"I take for stick the scraggedest,
The thorniest, knottiest, raggedest,
The thorniest, knottiest, snaggedest.
Be it buckthorn, be it oak;
I pluck the flowers so sweetly,
Leave knot and thorn so nately,
And for seven long days completely
It must soak, and soak, and soak."

There is a whole lot of philosophy in this. Our worst passions and most forbidding traits may become our ornaments if held in check and made to bless and not curse. We may well leave the knots "completely" if we will only use enough of the hard polishing to smooth them down. The great thing to remember, we must let the hard, forbidding sticks of character "soak, and soak, and soak."

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

The Premiums offered this week are well worth working for. Look at them.

To Our Shippers.

About May 1st last, we removed our business from the buildings 120-122 W. Broadway to larger and more commodious quarters at Nos. 265-267 Greenwich St., and 82, 84, 86 Murray St., and we duly sent to our friends in the trade a notice of our removal. Shortly after we vacated the premises (120-122 W. Broadway,) one Joseph M. McCaul, rented a portion of our old quarters, and hung out a sign, "Hildreth, McCaul Co., Jos. M. McCaul, Prop.," with other large signs to the effect that his business is "headquarters for honey, beeswax, maple sugar and maple syrup."

The mercantile agencies report that Jos. M. McCaul is the sole proprietor of the new business, and that he claims to have paid to one Henry P. Hildreth (who has no connection with our business,) a consideration for the use of his name.

We will not comment upon the act of leasing our old quarters and exposing thereon the sign, "Hildreth, McCaul Co.," further than to state that we have instructed our attorneys to apply for an injunction restraining the said McCaul from using the name of "Hildreth" in connection with his business in any manner whatsoever.

We value highly the good name and business we have established by many years of satisfactory dealing with our friends in the trade, and we therefore send this notice so that you may not possibly confound us in any manner with the so-called "Hildreth, McCaul Co."

Our firm name remains as heretofore, and all our business is carried on at our new quarters—

Nos. 265-267 Greenwich Street,
and Nos. 82, 84, 86 Murray St., New York, N. Y.

Respectfully yours,

HILDRETH & SEGELKEN.

Good Honey-Flow.

Bees are doing well, and are in good condition. The honey-flow is good, water better. From June 3 to June 15 it was cold and windy. We have had no swarms to amount to anything. I have taken off nearly 3000 pounds of honey. G. W. VANGUNDY.

Uinta Co., Utah, July 7.

Short Crop of Honey.

The basswood honey-flow is over with us, and a very short crop. We are having a drought in this part of the State, that is hurting everything. The pastures would burn. W. J. PICKARD.

Richland Co., Wis., July 13.

Queen-Rearing.

The greatest trouble in queen-rearing is making up the nuclei to receive the cells. Many good colonies have to be divided in forming these nuclei, and there is always a loss to the apiarist. I have used the following plan for a good many years, with very little trouble:

I have two extracting supers on every brood-chamber, and after the honey season is over I take from the top super two combs, and put two brood-combs in place of them. The next day I give them a queen cell, and raise the cover a little to make an entrance. As soon as the queen hatches the bees will gladly receive her. Mating soon takes place, and I have a laying queen in the super. As soon as the queen is taken out I destroy all queen cells, and the work is done.

Year after year I have succeeded in rearing a number of queens in this way without any loss or hindrance in my apiary.

Jamnicia. JOSEPH'S SMALL.

Do Bees Select Their Future Home Before Swarming?

This subject is attracting some attention among the readers of the American Bee Journal, and I have been amused at the various views expressed by "Rip Van Winkle." on page 429.

I have been a bee-hunter ever since the '60s and have found hundreds of swarms under almost every conceivable condition, from a hole in the ground to a whole lot of other places, and my opinion is that it depends altogether upon circumstances.

If the parent colony happens to be located near, or within a mile or so of a timber lot, and if the bees have visited it for honey, and the trees are large, with suitable holes to make homes for bees, if you are in those woods during the swarming season you will see bees looking the trees over. These searcher bees are from a colony near by about ready to swarm, or they are from a swarm that has clustered near by that may have come near the trees without discovering a home to suit them.

I have kept bees for many years, and have been situated near the timber and also on the prairies, and have studied their habits. On the prairie four miles from timber I have had swarms strike out, and they must have come many miles before finding even a bush to settle on, and they were first swarms, too. They certainly had not selected a future home. When located near the timber I used to go into the woods in early swarming-time and see the searcher bees looking the trees over for a home, and would find them cleaning out a hollow tree, or sometimes two or three of them, and have sometimes followed them from the hive to the tree they were preparing two or three days before, and in these cases, of course, they had selected their future homes before swarming.

Again, I have followed a swarm seven miles

through the timber, where there were fine places for a home for it, and would at last find it in an inferior place not fit for bees to winter in. This swarm went about five miles before reaching the timber, and had clustered twice before selecting a home. But had the parent colony been situated near the timber the swarm probably would have selected its home before swarming.

So, I think, as I said in the beginning, that it depends altogether upon circumstances, whether they select their home before swarming or not; and I have come to this conclusion from an experience second to none west of the Mississippi River, on this particular subject. If Mr. "Rip Van Winkle" doubts my source of information I can refer him to any bee-keeper in this part of South Dakota.

J. M. HOBBS.

Yankton Co., S. Dak., July 8.

Sweet Clover—White-Eyed Drones.

A few months ago I had the pleasure of visiting a bee-keeping friend, one of the veterans in our State, whose painstaking and methodical thoroughness in all that pertains to the craft may well be an inspiration to those of more slipshod ways. He is modest and unassuming, and as ready to listen as to talk. He remarked that he had seen nothing from me in the beekeepers for a long time, and I had to own it as a fact that the little creatures keep me so busy that I have not much inclination to write. They are doing better than usual for the time of year, and I ascribe that largely to the yellow sweet clover that I am growing. I have a small field of it, and also have it scattered in woods and corners. It blooms here early in June—just about a month ahead of the white variety, which I have had for years. It promises to be quite a boon to my locality, coming as it does when ordinarily there is little for the bees to gather from. I have had to feed bees in June more than once, but this year I must either divide colonies or take care of swarms.

I had been thinking that my enthusiasm was waning somewhat under the pressure of crowded hives, but it comes back to me when I get after a swarm.

I have been puzzled lately over some drones that seem to be normal, except that they have white eyes. I don't remember noticing any of that kind before, and don't know what to think of them.

MRS. A. L. AMOS.

Custer Co., Nebr., June 27.

Second-Hand Cans. Etc.

FRIEND YORK.—I notice on page 441 that "Afterthought" thinks it important to comment on an item contained in a private letter to you, which you thought proper to publish in May 16th issue. Now, there was no theory advanced respecting bee-keeping, nor anything else, but a simple statement of fact, and what point he seeks to make I am too dull of comprehension to discover. If he intends to cast discredit on the statement of fact, he simply advertises himself as anything but a gentleman.

It may be that the item "winged" him—as sportsmen would say—as he may be a dealer in EXPENSIVE Dave and Standard Oil Co. cans—any old rusty can that he can palm off on honey-eaters. When he talks about time or space to fill, and nothing with which to fill it, the idea may be aptly applied to the column over which he presides, in numberless instances which might be referred to.

For instance, take the item headed, "Mr. Doublet and Our Country." The entire Bee Journal might be filled with arguments, facts and figures, to show the falsity, or fallacy, of the idea intended to be conveyed, if one can be gathered from what he says. If foreigners come over here and invest their money, somebody gets it if they are successful, so much the better for every one concerned in the business, from the highest to the lowest laborer; if they finally sell out and take their money back to a foreign land, some one has made enough to buy them out, and has the business; if they invest in any of our bonds, their money goes into large business enterprises, like railroads, or manufacturing in-

dustries; if their bonds are finally paid with the accrued interest, it only shows success of great enterprises.

No one need worry, nor have any sleepless nights over our ability to stand all such drains upon our life-blood—the old "ox in the pasture" doesn't realize that it's even *my* turn. But why pursue the subject?

Again, referring to the "daughter thrown in," in the manner in which he does it. There are many wealthy Americans, as well as many who are not so wealthy, whose daughters, worthy of every mark of consideration and respect, exercise the right—as I presume they should—would claim for himself—to select a partner for life from among those they think proper, and many of them marry husbands of foreign birth.

But to return to the cans. Those cans were bought of George W. York & Co. How does "Afterthought" know, or what does he care, how many "dimes" were paid for, or lost on, them? Of what interest is it to him, or the public, whether much or little was lost on them, unless, as he suggested, he may be in the SECOND-HAND business?

WM. M. WHITNEY.

Kankakee Co., Ill., July 15.

Good Season for Bees.

This has been a very good season here, and the bees are doing nicely.

J. WARREN SHERMAN.

Solfolk Co., N. Y., July 12.

Dry and Hot.

I have 45 colonies of bees, all in fine condition, although it is very dry and hot, the temperature being 104 degrees in the shade. Yet my bees are gathering some honey from sweet clover.

JO DAVIES CO., Ill., July 16.

Selecting a Home Before Swarming.

Two years ago I had an empty hive under a shed not more than 10 feet from the working colonies. One day my wife said that she saw bees coming out of that hive, and wanted to know if I had put a swarm into it. I replied that I had not. That afternoon a swarm issued from one of the old colonies, and we put it into that hive. The next day a swarm came to us from the northeast, and settled on a small cherry-tree not more than 20 feet from where the empty hive had been. It looks very much as though that stray swarm had intended to take possession of that empty hive, but finding it gone they settled on the cherry-tree. (I got 'em.)

On June 15 I had two swarms go together, and in 17 days the brood-chamber was filled, and I took off 24 fine sections of clover honey.

YOT SG. BEE-KEEPER.

Logan Co., Ill., July 8.

Heavy Losses—Ahead of Dr. Miller.

I find that some bee-keepers in this locality have had bad luck, having lost all they had. A great many colonies died in the fall, or soon after, as there was no honey around here at that time. I saved 10 out of 22, and this is the first time I ever lost any in wintering.

My bees are swarming more than I want them to this season. I have one colony that has not swarmed in five years, and they have always stored more than any other two, but they are very weak now, and I think the queen must be worn out.

I have worked with bees, off and on, ever since I was a boy, and I am now 75 years old, and never have to wear glasses. I can take dog and gun and hunt from morning till night, and am as good a shot as ever. My wife is 74, and quite strong. We have been married 56 years, and have had 15 children. I think that beats Dr. Miller's 70 years.

I keep bees because I like them. Sometimes they are somewhat ugly, but if 500 were to sting me it would not hurt.

HENRY WHITE.

Humboldt Co., Iowa, July 1.

An Overgrown Putty-Knife.

This is a tool used with great satisfaction by S. E. Miller in the apiary. He tells of it in the *Progressive Bee-Keeper*:

Made of about one-sixteenth inch steel, $2\frac{1}{2}$ inches broad at the sharp end, tapering to about $1\frac{1}{4}$ inches 6 inches from end or where the handle commences. The handle is made of two half-round pieces of wood riveted on each side, the same as handles are put on butcher-knives or table-knives. It is ground alike on both sides, so that it does not matter which side is up when I go to use it.

When I get this blade between two bodies, or a body and cover, and begin to pry, it has to come, no matter how much propolis. The tool being large and strong (nearly a foot long) gives a great leverage, and no great effort is required in using it. I can take it slow and steady and bring two bodies apart without a snap. It will take the burr-comb from two top-bars at once. It is handy to clean bottom-boards, queen-excluders, and, in fact, almost anything where scraping is needed. I frequently use it to dig with when leveling up hives.

Improving Our Stock.

Here are some words well spoken by "The Worker," in the *Australian Bee*:

Were I forming rules for judging Italian bees, I would place the points about like this: Honey-gathering, 30; prolifiveness, 10; gentleness, 5; color, 5; total, 100. It is so much easier to breed for color than for honey-production, that it will be some time before all of the bee-keepers in our land get into line. Some will say, "Oh, the Italian bees are good enough as they are, so long as we keep them of the three-headed strain." Others will say, "We want our bees to look beautiful; they will get the honey if there is any in the flowers." This is a mistake a great many make. I have had a lot of people say to me:

"What is the use of all your fussing, and breeding this and that? If there is no honey in the flowers the bees can't get it, no matter where they are."

I admit that, but when there is honey in the flowers the good strains will gather much more than the poor ones will. It is not so noticeable in a good season as a rather poor one. Before I commenced breeding for honey-gathering my colonies would vary much in the quantity of honey stored. I remember one year one colony gave me over 100 pounds of honey, while others only gave 30 pounds, and the average of the whole was about 20 pounds per colony. How I wish I had that queen now.

By careful breeding I now have my bees as nearly alike as regards honey-gathering as one could desire. Last year there was scarcely a pound of difference in the whole yard, and it was only a fair season for honey. Brethren, let us be ever on the watch for the queen whose bees excel in storing honey, and then breed from her, thus ever improving our stock.

Stimulative Feeding in Spring.

This has sometimes been spoken of as a two-edged sword, cutting both ways. Practiced at a time when bees are tempted to fly out in bad weather only to be lost, it may tend to diminish rather than increase the number of bees in the hive. G. M. Doolittle gives in the *Progressive Bee-Keeper* another phase of the matter, as follows:

During all the past we have heard much of stimulative feeding, with no hint that such might be a failure at certain times, but from past experiments, and experience, I find there are times when feeding, or other stimulative

work, brings no adequate returns. The queen lays only as she is fed stimulative food by the workers, and the workers will feed her only this stimulative food when there is some reasonable prospect for a successful outcome. And while feeding will bridge over three or four days of bad weather, or even a week, yet there comes a time when they seem to lose hope and settle down on the firm determination that they will make no further efforts at "expansion" till they see some sign that there is to be propitious weather in the future. And during such long-continued, cold, wet spells as the present, I have found that the colony which was fed every day had very little, if any, more eggs or larvae in the hive at the end of two weeks than did the one having a reasonable allowance of stores, which had not been fed at all. But when we have fairly comfortable weather, but a dearth of nectar from no flowers being in bloom, or those in bloom not yielding any nectar, then good results can be obtained in feeding, or other ways of stimulating.

Close Imitation of Natural Swarming.

This is given as follows by G. M. Doolittle, in *Gleanings in Bee-Culture*, in a conversation with a neighbor, the first question being asked by Mr. Doolittle:

"Have you any queen-cells on hand?"

"I suppose there are plenty in any of those hives which have swarmed during the last week."

"You will see why I asked about the queen-cells before we get through. Now, to the plan: Take a box holding from three pecks to a bushel, and place it on a wide board a few feet from the hive you wish to make the swarm from, raising the front edge on a little block, enough so the bees will run under. Now open the hive you wish to make the swarm from, and find the queen, caging her on one of the combs, when all the frames are put back in the hive again. If you do not see plenty of unsealed honey, uncap some along the top-bars of the frames and close the hive. Now blow in quite a little smoke at the entrance of the hive, and rap on the sides of it as you would in driving bees, rapping at intervals, and leaving the entrance open so that the bees returning from the fields may enter the hive. In from five to eight minutes open the hive and take out the frames and shake the bees in front of the box, and thus continue till you get at least three-fourths of the bees in the box. When you come to the frame which has the queen on it, place her at the entrance of the box, and let her run in with the bees. When you get the desired amount of bees in the box, put the frames back in the hive and close it."

"Why do you run the bees into such a box instead of into a hive all prepared for them?"

"If you will not be impatient I will tell you so you will see the reason. Now, we will suppose that you have three-fourths of the bees and the queen in your box. You are next to take the box of bees to the shade of some tree and lean the box against the tree in an inclined position, with the open side of the box outward, leaving it there three-quarters of an hour, at which time you will find them clustered in the upper part of the box as they would be on the limb of a tree, if they had swarmed naturally. During the three-quarters of an hour, if you have more to make, keep on making from other hives in the same way. At the end of the time, give the bees that are in the box, the same as you would give any natural swarm. Put the hive on the stand you wish them to occupy, and see that all of them go into the hive, and they will stay and work the same as a natural swarm would."

"Then this leaving them the three-quarters of an hour with the open side of the box out is to make them think they have left home, so they will mark their location as does a swarm?"

"Exactly."

"I see now why mine would not stay when I shook them into a hive. But what about what is left in the old hive?"

"The next day, after making such a swarm, give the old colony a queen-cell from one of

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2; or, one Tested Queen free as a premium for sending us FOUR new subscribers with \$4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

Please Mention the Bee Journal when writing Advertisers.....

the hives you say have such, giving cells from the colonies which have those the nearest ripe, and the work is done. If you have stopped to think as we went along you will see that you have bees of all ages in your "made swarm," just as there would be in a natural swarm, and that each bee has its sac full of honey the same as they do when they come out themselves, the drumming causing them to fill themselves full more completely than they do when swarming. By being left three-quarters of an hour to cluster in the box they mark their location anew, the same as a natural swarm, as you expressed a few moments ago."

"But is the old colony in as good condition as it had swarmed naturally?"

"I think so, fully, and more so; for in natural swarming the first young queen does not emerge from her cell in less than seven days, unless the swarm has been kept back by bad weather; even our made swarm, and a ripe cell being given, they will have a queen in two days from the time of making. If preferred, and you have them, a laying queen can be given to the old colony."

"Why would not this be a good plan to work an out-apiary, where there is no one to take care of swarms when they issue?"

"It would. And it is equally adapted for those who can not be at home between the hours of 8 a.m. and 4 p.m. to care for their bees when swarming naturally."

—THE

Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without **THE BEE-KEEPER'S GUIDE**.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

Wanted

A position as assistant in an apiary; boy 17, strong, experience. Address, ALBERT RICHTER, 157 Rhine Street, CHICAGO, ILL.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.

Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This nicely illustrated, contains 100 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadaud.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Honey-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. A. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book: 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Tros. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey," 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honigerzeugung, nach der neuesten method der German, by J. L. Evers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, hard cover. Price, 50 cents.

Bee-keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper.

Bee-keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yield of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

1901—Bee-Keepers' Supplies!

We can furnish you with everything that you need for your apiary at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price and freight added. Send for our 1901 Catalogue. M. L. HUNT & SON, Bell Branch, Wayne Co., Mich.

Please mention Bee Journal when writing.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 18.—Choice white comb honey is arriving rather more freely and brings 13c. There is no accumulation at this writing, as receipts sell within a week after arriving, some of them on the same day. Amber grades bring about 12c. Extracted dull and slow of sale at anything over 7½c. Beeswax steady at 3½c with good demand. R. A. BURNETT & Co.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from ¼ to 1 cent per pound. C. H. W. WEBER.

BOSTON, June 23.—There is practically no comb honey in our market, and owing to warm weather very little call for it. Are expecting some new comb early next month. Market for extracted dull, at ½¢. BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00. PEYCKE BROS.

NEW YORK, July 8.—Our market is practically bare of comb honey, and demand good for white comb. Fancy stock sells readily at 15c; No. 1 white at 13½¢, and amber at 11½¢. Extracted not in much demand, with plenty of supply; white, 6½¢; light amber, 5½¢; dark, 4½¢. Beeswax firm at 24c. HILDKRETH & SEGELEN.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts or stocks and little demand. It is between seasons now. Prospect of good crop in this vicinity from what bees there are left, the greater portion having been killed by foul brood exterminators. H. R. WRIGHT.

DETROIT, July 18.—Fancy white, 15c; No. 1, 13¢; 14c; no dark to quote. Extracted, white, 6½¢; 7c; dark and amber, 5½¢. Beeswax, 20c. M. H. HUNT & SON.

BUFFALO, July 10.—No demand for honey yet unless a very small amount of fancy white at perhaps 15¢. Some old lots still about, unsalable, almost, at 6, 8 and 10 cents. Beeswax, 22¢. BATTERSON & Co.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being granulated. Sales are light at 15 cents for best grade No. 1 Colorado. Amber, 13c. Beeswax firm at 25¢. W. R. CROWMELL PRODUCE CO., Successors to C. C. Clemens & Co.

SAN FRANCISCO, June 19.—White comb, 11½¢; 12½¢ cents; amber, 10½¢; 11c; 12c. Extracted, white, 5½¢; 6c; light amber, 4½¢; 4c; amber, 3½¢; 4c. Beeswax, 26¢. Market shows no quotable improvement, but there are no large quantities obtainable at the prices generally named by dealers. In a small way, for especially desirable quantities, slightly higher prices than are quoted are being realized.

Wanted Fancy White Comb Honey in no-drip cases; Also Extracted Honey. State price, delivered. We pay cash. Front & Walnut Sts., Cincinnati, Ohio. Reference—German National Bank, Cincinnati. 2-A171 Please mention the Bee Journal.

BEES WAX We will pay 26c. cash, per lb. for pure, bright yellow, 20c. cash, per lb. for pure, dark beeswax delivered here. CHAMBERLAIN MEDICINE CO., 115 N. Monmouth St., Phila. Please mention the Bee Journal. 27A131

Wanted.

Comb and Extracted Honey. Will buy honey no matter what quantity. Will sample of extracted, state quality of comb honey and price expected delivered in Cincinnati. I pay promptly on receipt of goods. Refer you to Brighton between East and 15th Sts. C. H. W. WEBER.

Red Clover Queens

We have been telling you through our advertisements of the superior stock of queens we are furnishing this year, and we have abundant testimony from others corroborating our opinion. Look at the following which is only one of the numerous endorsements received.

July 5, 1901.

The bees are working as I never saw them work before, and already there is over 100 pounds of honey in the hive, and all from clover. I am led to believe that long tongues and good working qualities go together.

Yours very truly, OREL L. HERSHISER,

Supt. N. Y. State Apiarian Exhibit, Agricultural Building,
Pan-American Exposition, Buffalo, N. Y.

This refers to a colony of bees on the Pan-American grounds with one of our Tested Red Clover Queens reared last season.

Our Prices are as follows:

Gleanings in Bee-Culture one year and one Untested Red Clover Queen, \$2.00.

Gleanings in Bee-Culture one year with Tested Red Clover Queen, \$4.00.

Gleanings in Bee-Culture one year with Select Tested Red Clover Queen, \$6.00.

If you want something good you can not do better than to order one of these queens. All orders are filled promptly. No extra postage on these offers to foreign countries.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one (of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

THE THOUSAND MEMBERS for the National Bee-Keepers' Association are coming. Since our last report we have received the membership dues from the following:

B. H. TRIPP.

H. A. DOTY.

REV. M. MAHIN, of Henry Co., Ind., wrote us July 23, as follows:

"My bees have boomed this summer. When I get time I will tell you more about it. In a month I will complete the 60th year of my ministry, and I can easily preach four or five times a week."

Mr. Mahin deserves to be congratulated on his good health and ability to continue in his work. May richest blessings be his.

THE OFFICIAL EMBLEM of the Pan-American Exposition was designed by Raphael Beck, of Buffalo. It was accepted as the most artistic and suitable from several hundred designs submitted, and has the special merit of effectively symbolizing one of the chief

Official Emblem—Pan-American Exposition.

purposes of the Exposition, which is to bring in closer social and trade relationship the Republics, States and Territories of North and South America. The emblem shows a fair maiden typifying the North, extending a friendly hand to clasp that of her brunette sister of the South, thus forming a bond of continental sisterhood, and establishing a unity of sentiment and interest among the countries of the Western Hemisphere.

MR. E. M. HAYES, of Sauk Co., Wis., began to keep bees ten years ago, with one colony in a dry-goods box, somewhat larger than the hive he is now using, and the bees wintered well in it without protection. He now uses the 13-frame Langstroth hive, principally, and has adopted the tiering-up plan.

While he does not consider his an ideal location for bee-keeping, he never gets less than 60 pounds of honey per colony, and he has secured as high as 160 pounds per colony, and some increase. He sometimes gets light honey from clover and bergamot; there is no basswood in reach.

Mr. Hayes says that buckwheat is a much more valuable honey-plant than many give it credit for being. It comes late in the season, thus giving all colonies that were weak in the spring a chance to build up strong. While some think it fit only for manufactur-

ing purposes, he has a good many customers who buy it year after year for table use. Some buy it because they prefer it to white honey, and some because they can get it a little cheaper.

The greater part of his dark honey he sells in barrels at 6 cents per pound, f. o. b. there. The last two years he has sold some of it at 7½ cents per pound.

The illustration on the first page shows a part of his apiary, the single-walled hives being in the cellar at the time the photograph was taken.

THE BUFFALO CONVENTION, as has been announced several times, is to be held Tuesday, Wednesday and Thursday, Sept. 10, 11 and 12, in the Lecture Room of the Buffalo Society of Natural Sciences, in the Buffalo Library Building, located at the corner of Washington and Clinton Streets, near the city business center.

Secretary Mason has sent us the following additional "good thing" on the program:

EDITOR YORK:—Since sending you the last notice of the Buffalo Convention, which appeared on page 435, I have invited Mr. H. W. Collingwood, editor of the Rural New Yorker (who is a staunch friend of bee-keepers and of our Association, as well as a pleasing speaker), to give an address at the joint session, on "The Pomologist and the Bee-keeper." Of course, he'll be at the Pomological meeting, and I doubt not will be glad to talk for us.

Every indication is that we are to have a good meeting at Buffalo. A. B. MASON.

We are glad to see that the Buffalonian people can count on a good-sized crowd of bee-keepers. Of course, Supt. Hershiser will have good arrangements made to care for all, and at reasonable rates. If he doesn't he'd better get ready to go over the Falls of Niagara.

MR. JOHN M. RANKIN, of Lansing, the State inspector of apiaries for Michigan, writing us July 20, said:

"I am finding foul brood, good and plenty, in every locality I have been in thus far. Fully 75 per cent of the apiaries I have visited have been more or less diseased."

Surely, Michigan needs a foul brood law and an energetic inspector. Now that she has both, her bee-keepers may expect to see the bee-disease "move on"—perhaps over the Canadian line, only to fall into the hands of that veteran bee-disease killer—Wm. McEvoy.

PROF. A. J. COOK and family have been taking an outing in the mountains of San Bernardino Co., Calif. In a letter dated July 19, he wrote:

"We are having a lovely time here in the mountains. I wish you and all the American Bee Journal friends were with us."

Oh, but wouldn't Prof. Cook have a crowd around him if all the American Bee Journal friends were to congregate there? Well, there would be several present—and it would be mighty hard to find Prof. Cook in such a crowd as that would be.

"THE END OF THE DEAL" is the title of an unusually good business serial story which is to begin in an early number of the Saturday Evening Post, of Philadelphia, Pa. A famous transaction on the Chicago Board of Trade is the basis upon which the author, Mr. Will Payne, has founded this striking romance of the wheat pit. A charming love story runs through the stern and stirring plot.

* Editorial. *

Honey in Cans vs. Barrels.—Although we fear having our motive misjudged, we feel that we ought to say another word on this important subject. We certainly would refrain from referring to it now were it not for the fact that additional experience simply confirms us in the belief that extracted honey ought to be put into 60-pound tin cans rather than in wooden barrels.

We received two 400-pound barrels of very fine honey from Florida recently, and this after we had almost positively declared that we would not purchase any more honey in barrels. One of the barrels leaked, as usual! Both absorbed a number of pounds of the honey, also.

True, a tin can will occasionally burst, and thus cause leaking. But when it does, you can't lose more than 60 pounds out of one 60-pound can. But a barrel—well, we have more than once seen over a half-barrel of honey lost through leaking, or from the head bursting out.

Yes, tin cans do cost more than barrels, but they are worth more, and for several reasons. The honey in them can be re-liquefied without digging it out and putting it into something else, as must be done with honey in a barrel. Honey in 60-pound cans is in better shape for the cash honey-dealer to handle. It is a quantity that many a family feels it can afford to buy at one time. Other excellent reasons might be given.

It may do to put dark or cheap honeys into barrels, but the fine white extracted honeys we think ought always to be put into 60-pound tin cans. We believe the day will soon be here when such honeys will be required in tin cans, and perhaps at a slight advance in price over that of the same grade in barrels.

Another Victory for the National.—The National Bee-Keepers' Association has won another notable victory in the courts. General Manager Secor sends us the following condensed account:

EDITOR AMERICAN BEE JOURNAL:—

In December, 1900, the city of Rochester, N. Y., had under consideration the passage of an ordinance prohibiting the keeping of bees within the city limits. W. R. Taunton, a member of the National Association, living in the city, and whose business and liberties would be interfered with by such an ordinance, appealed to the general manager for advice and assistance. Such printed matter as it was thought would be of service to him was forwarded, and, with the assistance of

able legal counsel, Mr. Taunton succeeded in having the proposed ordinance withdrawn.

But in April, 1901, the matter was revived, and through the persistent efforts of one of the aldermen, and in spite of all objections and remonstrances, the ordinance passed.

Mr. Taunton was advised not to remove his bees, and assured that if he got into trouble the Association would defend him.

Mr. Marks—a director of the National Association—was requested to go to Rochester and make a complete investigation. He did so, and reported that in his opinion Mr. Taunton was handling his bees in a manner not to annoy neighbors, and thought he ought to be protected.

In corresponding with our attorney, Mr. Dutcher, the latter stated that the police Judge, before whom the case was likely to come, was an able man, and thought the Association would better risk it there.

The case was tried upon a warrant of arrest for refusing to comply with the ordinance, and the Judge of the Police Court rendered his decision, setting aside the ordinance, and discharged the defendant.

The Judge did not file a written opinion. The counsel's brief is enclosed herewith.

EUGENE SECOR,
General Manager Nat'l B. K. Association.

The above case was referred to editorially on page 323. Surely, another victory is won by the "Old Guard." But such victories can not be won without expense to the Association. And the only source of revenue is from membership dues. So every bee-keeper who cares for his own rights, or that the rights of others shall be protected, should be a member of the National Bee-Keepers' Association. You may not have to call on it to aid in defending you—and then you may. No one can tell at what time he may be unjustly prosecuted or threatened. Better "get in the dry" before it rains, and thus take no chances of being caught unprotected.

See the first column of the second page of every issue of the American Bee Journal for information concerning the Association.

Forcing Honey Into the Super.—The Australian Bee-Bulletin says:

Putting frames with eggs and unsealed larva at the outside of the cluster the bees don't want to store right in the middle of the brood-nest, so put all surplus in the super.

That will work all right some of the time, but when a heavy flow is on, bees will often allow solid combs of honey right in the middle of the brood-nest.

Bottling Honey.—J. R. Schmidt tells in *Gleanings in Bee-Culture* about the practice of C. H. W. Weber, the successor of C. F. Muth, who succeeded in building up a good trade in granulated honey. Instead of following that up, Mr. Weber goes to the other extreme, and sends out honey that *will not granulate*. That he succeeds in doing so

"may be readily seen from the fact that some honey put up and sealed last summer had been kept on ice since bottling, and after passing through the present winter, is just as clear as it was the day it was put up, and not a case of granulated honey had to be replaced this winter."

The secret lies in putting up the honey in much the same way that fruits are put up—having everything hot at time of sealing. The apparatus used by Mr. Weber cost about \$100, but it is probable that apparatus for putting up on a smaller scale might cost very much less. There is for heating the honey a tank within a tank, with a three-inch space between the two for water. When the granules are all melted out of the honey, and when for five or ten minutes the honey has been kept at 180 degrees, it is drawn off into the bottles, the cork is hammered in with a mallet of solid rubber, and then dipped into a melted preparation of rosin and beeswax, making it perfectly air-tight. If honey thus put up will keep indefinitely without granulating, it will much simplify matters for those who now go about taking up from grocers bottles of honey for re-liquefying.

An Artificial Swarm is thus directed to be made, in Blenvenature:

Take from the hive all the combs with adhering bees, except the comb on which the queen is found and a comb of honey. Fill up the hive with frames containing starters, and close the hive. The combs taken from the hive, with their adhering bees, are to be put in a new hive and placed on a new stand, having water furnished to them for four or five days. The field-bees will all join the old queen on the old stand, and the colony on the new stand will rear a new queen.

In this country it would be considered a gain to give the new colony a laying queen or a mature queen-cell.

Steam Wax-Presses vs. Hot Water.—Ramblar lauds steam wax-presses in *Gleanings in Bee-Culture*, but thinks they may be excelled by those in which the material while in press is all the time kept under hot water. These are in use in Germany, where steam presses have been in use a number of years, and it is said that those who have tried both prefer the hot water.

A Cheap Bee-Stand certainly is the one recommended by *Loyalstone* in the *Australian Bee-Keepers' Review*. He says, "Nothing better, and cheaper, to my mind, than making mounds of earth, well battered down, rising about four inches above the lowest level of the ground." In some localities, perhaps rather in some soils, this may work all right.

Moving Bees Into the Buckwheat Fields.

BY F. GREINER.

PERHAPS the reader may think that there isn't anything to be said on the subject of moving bees into buckwheat for "moving bees is moving bees," and what applies to moving to out-apiaries in the spring also applies to moving into buckwheat sections. I admit, in a measure, this is true, but when we take into consideration that our bees toward August 1 are in altogether different condition than we find them in the spring, it may not seem out of place to offer some suggestions in regard to how we may manage this matter.

If there has been a honey-flow previous to buckwheat time, our hives will be found quite heavy, and the handling of them is not mere boy's play; they are also overflowing with bees, making it necessary to give more ventilation than is necessary in the spring moving. These different conditions must be met. My friend, E. H. Perry, of this (Ontario) County, N. Y., has been instrumental in bringing out a plan by which the moving of these heavy hives may be avoided, so that more colonies may be carried on one load, etc. In the following I will give the details of the plan, with some modifications:

Let us suppose the buckwheat honey-flow commences Aug. 5. We then commence to get ready about Aug. 1. It will be necessary to have as many empty hives on hand as we wish colonies to move. Said hives should be of the capacity of five or six Langstroth frames, and be filled with comb. We also need ventilating screens. These may be made by taking hive-bodies and sawing them into 2½-inch sections, nailing wire-screen over each. These ventilators answer a double purpose when fastened to the top of the hive. In the first place, they give plenty of air while moving; secondly, they allow the smoke to escape and give ventilation while driving the bees out of their old home into a new one, which is our first step in the preparation for moving our bees into the buckwheat section, for we prefer to leave all these heavy brood-combs at home, and take only the naked bees. So, accordingly, we proceed.

The "driving" requires but little time, but some skill. The colony is raised up from its bottom-board and so placed as to give us easy access to the underside of the frames. The new hive with combs, the section-case and the ventilating screen, all fastened together, are placed on top, and by the judicious use of smoke from the bottom, and pounding on the brood-chamber, the bees are forced up into the empty hive, etc., in a very few minutes. When this is accomplished we lift off the new hive with fixtures and bees, and place it upon the same bottom-board and stand the colony previously occupied. We put on the cover and let it remain thus until we are ready to move three or four days later. We wish to let the bees become acquainted with, and adjust themselves, to the new state of things before moving them, or else some might swarm out as soon as opened up in the new location. Occasionally one of the colonies will swarm out the next day after "driving," and must be hived back with queen secured by an entrance guard.

The old hive full of brood and honey is placed right back of the hive containing the bees, for a little while, perhaps an hour, not more, or till we have evidence by the behavior of the bees of the forced swarm that their queen is with them. When we feel sure a queen is left in the old hive, we are obliged to make a search for her, and when found place her where she belongs.

The hives with their brood-comb may now be placed around on other colonies, left at home, two or even three upon a single colony. Excluders are used to keep the queen from below to enter the brood-chambers above. We manage these sets of brood-combs for increase, as explained later on.

The question might be asked, Why not furnish these forced swarms only with foundation starters? Indeed this might answer as well, or even better, as far as the securing of comb-honey is concerned. However, it is not safe to move newly-hived swarms long distances—the combs give the bees a chance to cling to during the journey; and then we wish some honey stored in these small brood-chambers

for wintering. We are quite sure to accomplish this end by furnishing the combs instead of starters.

When selecting the colonies to be moved we pick out such as have old queens. We may have to double up in order to get all colonies in proper shape for winter; if all have old queens we avoid the possible sacrifice of young queens. When the season is getting near its end, this doubling-up may commence. It can better be done at this time than later when no more honey is coming in from the fields. Instead of this doubling-up we may re-unite them with the parent colonies, providing we do not wait too long before we take them back to the home yard.

It has not been fully explained just what was done with the sets of combs full of honey and brood, except that they had been placed upon other colonies over queen-excluding honey-boards. Our practice is to leave them alone for five or six days. Quite a good many young bees will then have hatched, and the larger part of the brood is sealed. We then take them off, bees and all, place each one on a bottom-board and move to a new location. If we have any queens on hand, we supply them with such; if not, we have taken the precaution 10 days previously and started queen-cells from our breeding queens. These are then just ready, or ripe, and each new-formed colony receives one. In due time these will hatch, and the young queens will fill the hive with brood sufficiently to insure a good lot of bees to go into winter quarters. If they should not be as strong as desirable, then those colonies brought back from the buckwheat pasture may be united with them as mentioned. We kill the old queens, of course; thus we have practically requeened all our colonies that were moved into the buckwheat.

I can recommend the above plan as one giving us better results in comb honey than any other, and an increase in bees, if we desire the increase. Ontario Co., N. Y.

Advertising High Values for Queen-Bees.

BY FREDERICK B. SIMPSON.

HAVING been much interested in the recent discussions regarding high values for queen-bees, I will venture to give some of my ideas on the subject, and if I am mistaken I trust some one will show me wherein the errors exist.

Naturally, most criticisms have been directed against the A. I. Root Co., and personally it is of course no one else's business how they advertise; but from another viewpoint their extensive business interests place them in a position in which they are expected to represent all that is good, practical and progressive in apiculture, and their acts become a proper subject for public discussion, especially as by imitation these acts become much more far-reaching than would seem possible at a first glance.

Custom has made \$5.00 the standard selling price for a "best breeder." The qualifications of such a queen vary greatly with the seller. For instance, I last spring purchased one from a man who gave me her pedigree for two generations, and the honey-yield of herself, her mother, and her grandmother, and also indicated where the strain originated. On the other hand, a New York breeder sold me one before fruit-bloom this season, and said she emerged last August (last year being the worst in 33 in this State), therefore greatly restricting the opportunity for determining her value as a worker-mother, let alone a queen-mother. I am merely pointing out the variation, as I have no fault to find, for I think the buyer of such queens will average fully as much satisfaction and return for his money as buyers of any other kind of well-bred live stock.

I have always thought bee-keeping quite a staid, conservative and dignified calling, far removed from those expensive avocations which are indulged in solely as recreations. I have felt that the bee-keeper usually applies the same amount of business ability to his avocation as he does to his regular calling, whereas the faddist, or he who is in search of recreation only, tries to get away from his business and commonly fails to make a financial success of his fad. The future of bee-keeping will depend largely on what is now being done, and if we are to continue to advance, perhaps slowly but steadily, it is well for all to look to it that they do nothing that will have a tendency to make bee-keeping or any branch of it a mere fad, or to allow our bee-papers to make any approach towards yellow journalism.

By their \$200 valuation the Roots have obtained a great deal of free advertising, but as this has been largely by

adverse comment it is doubtful if it has paid well, and I hardly believe they knowingly used this valuation for the purpose of gaining such notoriety. In the American Bee Journal for June 20, Mr. Doolittle gave us some figures, but as he failed to notice that the mother of the drone with which a queen mates is entitled to probably the same share in the results as the queen's mother, and also that the mother or mothers of the drones with which the breeding queen's daughters mate, are also entitled to some share, his figures are of little value. Some years ago I tried to estimate the profit and loss in the case of horses, by the returns and expenses of their parents and produce, but I gave it up as a bad job, and I think the same fate will follow such estimates regarding bees. Possibly some one who is capable of compiling insurance statistics could help us out.

In regard to this matter, I believe the Rooters are primarily merely guilty of bad advertising, but by their influence I believe they are establishing a faulty precedent. For instance, it is unlikely that the average bee-keeper who will buy queens of them, would refuse \$5, or at the most \$10, for his best queen, at the same time he is proud of his best queen, and he naturally doubts whether he can purchase her equal. He does not know her monetary value, but he does know her comparative real value, and if she has proved extra-good it is highly improbable that any one's "say so" will convince him that there exists a queen which is really worth from twenty to forty times what he would take for her, especially as there is no logical reasoning back of the advertiser's estimate. If an advertiser fails to convince it will fail to sell the goods, and in this case it will likely cause antagonism. All things considered, and realizing the high reputation and great experience of the advertisers, would not the mere straightforward statement that this queen has proven beyond a doubt to be "by far the best breeder that we have ever owned"—would not this, or some similar expression, coming from such a source, make a far stronger, higher and more acceptable and pleasing appeal, and might it not sell more goods?

It strikes me as quite an innovation for one to advertise anything that he finds it necessary to warn any portion of the public against purchasing, and the rhetorical figure including the pig and the wheelbarrow, is likely to cool the ardor of some enthusiastic amateur. Why the beginner with but few colonies should not get comparatively as much satisfaction out of such queens as the other bee-keepers, I can not see. Naturally, he will not have as much chance for comparison as the large home-producer, which perhaps in three cases out of four may prove favorable to the queen; but he will not ordinarily put so much money in a queen without giving it careful previous consideration, and having purchased a queen at the highest price from a reliable firm, it is not likely that he stands quite a little more chance for satisfaction than the big man? To put it plainly, that warning looks to me like a real insult to beginners, many of whom will become our best amateurs; and who has more time for research than an amateur? Consider the proportionate amount of advice which has been made in photography due to the researches of amateurs as against professionals (although there are millions who are mere dabblers), and should not everything be done to encourage and stimulate the enthusiasm of amateurs in bee-culture? No, Mr. Root, you ought to balance that by saying something real nice in favor of amateur "enthusiasm," and if the beginner is "begigged" to buy one of your high-priced queens, please let him do so, for, just think of it, if he did not have the chance he might get to drinking and spend that money in whiskey!

But in Mr. Doolittle's article, above mentioned, does it not look as if he were hurling missiles from a very fragile point of vantage? To show the power of example, I will merely mention that I have recently noted four different advertisements in which the greatest inducement offered to secure purchasers is the Root Co.'s opinion of the monetary value of the queens' grandmother!! Another uses Doolittle's estimate in the same way in regard to the mother of the queens he sells, except that Mr. Doolittle was doubtful, and said, "If there is a breeder worth \$100, this one is"; still another does likewise as to Mr. Doolittle's assumed monetary value of the grandmother!! And if my tastes ran that way, and if I were selling queens, I would quote what the same gentleman wrote me of a queen I bought of him—"This queen is worth fifty dollars to any one as a breeder."

Now, so long as people will attempt to place monetary values on queens, are they not just as much to blame as those who merely quote them? I far more highly prize the

opinion of one man who sold me a queen, and said, "She is the best breeder we ever sent out." I know the man to be honest in his opinion, and therefore that he really believes I have the best queen that he ever sent out up to that time; whereas, if he had valued her say at fifty dollars, there would always be a doubt as to whether or not he had sold another that he valued at one hundred.

In view of the fact that it is really impossible to fix with any degree of accuracy a monetary value on a queen-bee, could not our veterans and leading lights who stand for all that is upright and honorable in apiculture, afford to set a good example and be sufficiently philanthropic to forego the pleasure of using such alluring figures, and, by failing to assume such values, in a measure to discourage the use of them for advertising purposes?

Queens are being advertised up to \$25, and the scale of prices is based on an arbitrary standard the value of which is unknown—as I understand it they are not even guaranteed to be "best breeders." Now, I believe that a "best breeder" averages the value placed upon it up to \$5; but it seems to me that if Mr. Doolittle's contention that only one queen in four is equal to her mother (and I see no good reason to doubt such a statement), and it is evident that where a queen is inferior it shows a lack of progression, and that the offspring are likely to keep on retrograding, it would seem that there is a great tendency towards a lottery in this scale of prices, and that satisfaction ought to be guaranteed on all queens sold for higher prices than best-breeder rates, so that by returning a queen the purchaser could get his money back, for, if Mr. Doolittle's experience is repeated, only one man in four will get thorough satisfaction.

As to the scale of prices, I have puzzled over it without any satisfactory results at all. Will not some one please tell me how you work it out? This is all I can get

A queen giving bees of .19 tongue length is worth.....	\$10
" " " " .20 tongue length is worth.....	"
(a \$5 increase).....	15
A queen giving bees of .21 tongue length is worth.....	"
(an increase double the last or \$10).....	25
Therefore, a queen giving bees of .22 must be worth.....	"
(increase double last, or \$20).....	45
and it follows that a queen giving bees of .23 tongue length is worth.....	85

That is to say, that the \$200 queen is only worth \$85, and her bees would have to have a tongue length between .24 and .25 to be worth \$200.

Or, let us assume that she is really worth \$200, and using the same scale of increase as we have above (between .22 and .23 it was \$40), we get the following values:

.23 is worth \$200; .22, \$160; .21, \$140; .20, \$130; .19, \$125.

From which naturally follows the query, How can they afford to let them go at the advertised prices?

Allegheny Co., N. Y.

[Since the above was written, Editor Root has announced that his firm will hereafter place no values on breeders which they propose to keep and will not sell; therefore a portion of the above becomes inapplicable, but as "there are others" it is deemed best to publish the article in full as written.—Editor.]

Brood in Sections—How to Avoid it.

BY G. M. DOOLITTLE.

WHAT is the cause of bees filling the sections with brood, and drone-brood at that? What is the remedy for it? I put on one surplus arrangement of sections some time ago, thinking that the bees were crowded for room, and perhaps would be forced to swarm when there was no bloom to sustain the swarm, and to-day I find the above results. Would you destroy the drone-comb, or shave off the heads of the drones in the cells? Please tell us through the columns of the American Bee Journal, as I think others would be benefited as well as myself.

ANSWER.—The querist seems the more surprised that the brood found in the sections was drone-brood, while if I should find any but drone-brood in the sections I should be surprised perhaps more than he, for I have yet to find worker-brood in sections, unless the colony was a new swarm and commenced their brood-nest "upstairs" when they began to build comb, as is sometimes the case where sections filled with foundation are placed on the hive when the swarm is first run in, with nothing but starters or empty frames below. Where swarms are hived on empty frames, the sections should not be put on till the bees get

well started at comb-building below—say in three or four days after the swarm is bived, unless a queen-excluder is used between the frames and the surplus arrangement. But where frames of comb or frames filled with comb foundation are used below, then the sections can be put on at the time of hiving the swarm, if desired.

But as to the cause of drone-comb and brood in the sections: If, as is usually the case with most of the bee-keepers of the present time, the questioner has restricted the drone-comb below, the natural consequence would be drone-brood in the sections, if the bees were allowed to build combs in the sections without the use of foundation, and especially so with a light flow of honey and plenty of pollen: for at such times the bees rear large quantities of brood, and prepare for swarming by starting as much drone-brood as possible, the same being limited only by the amount of drone-comb the queen has access to, and if she had little below there would be all the more incentive for her to occupy that being built in the sections.

Having spoken of the cause we will now proceed to the remedy. There are two ways to remedy this matter; and the one which I use most is the filling of the sections with very thin section foundation. This keeps all drone-comb out of the sections, and where there is no drone-comb there will be no drone-brood, providing we have a good, prolific queen; consequently this trouble with brood in the sections is remedied by thus using sections full of foundation having the worker-size of cells. Then, by thus using sections filled with worker foundation, we have very much nicer section honey as to appearance, after the sections are finished by the bees, for the capped combs having the worker size of cells are much more beautiful to look at than those of the drone size, as all who have compared the two side by side are willing to admit.

The other plan of keeping the queen from the sections is by the use of the queen-excluding honey-board between the sections and the brood-chamber. This will effectually prevent brood in the sections at any and all times, but such honey-boards are quite expensive, both in time of putting on and taking from the hive; room for storage when not on the hive, as well as in the money used in the purchase, or of the material from which to make; for they do not do away with the undesirable looks of the finished product, unless the sections are filled with foundation; besides, many claim that they should not be used in any event, on account of the believed lessened amount of our honey crop on account of the bees being loth to pass freely through the perforated metal. Regarding this latter claim I have my doubts as to its correctness, but consider all of the others as important.

Having given the remedy, what shall be done where we find brood in the sections before we knew of, or have applied, the remedy or preventive? This all depends upon what stage the brood is in when we find it. If it is found before any of the brood is sealed over, we have little waste except our time in taking the sections from and putting them back on the hive again, for it is well known, that, if this unsealed brood is taken from the bees and kept in a cold place for a week, the same is dead, and such dead brood will be removed by the bees as soon as they have access to it. My plan used to be, before I learned of the prevention as given above, to take sections, found with eggs and unsealed larvae in them, to the cellar, and there leave them four or five days, when they were returned to the hives again, and if the queen did not deposit more eggs in them, they were filled with honey, and when finished were as good as if no brood had been in them.

If the brood in the sections has been sealed long enough so that the larvae have begun to spin their cocoons, then the best thing to do is to cut the comb, or that portion having brood in it, from the sections, for honey stored in combs having cocoons in the cells is not just the thing for table use, nor to put on the market, unless this honey is separated from the combs by the use of the extractor, even though the same be sold as a second or third grade of comb honey, which it would have to be if sold at all, on account of the dark color the cocoons would give to the combs. It is never best, under any circumstances, to put upon the market that which will tend to injure the same, as is always the case by putting on honey of very inferior quality.

Onondaga Co., N. Y.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

(Continued from page 453.)

No. 4.—Some Reminiscences of an Old Bee-Keeper.

BY THADDEUS SMITH.

HAVING Italianized my little Island apiary, I now found myself in a favorable position for rearing pure Italian queens for sale, without a possibility of having them mated with black drones, for, as far as I could ascertain, I had the only bees on the Island, and it was an occupation that I knew I would greatly enjoy, and there ought to be money in it at less than half the price that I paid for my queens. Then why not do as they were doing on Kelley's Island? I concluded that I would, and accordingly began preparation to become an Italian queen-bee breeder.

I spent the next winter in Kentucky at my old home, and in order to advertise my queen-rearing establishment a little, I talked bees, and wrote articles for the State agricultural paper on the "New Era in Bee-Keeping," "The Movable-Comb Hive," "The Introduction of the Italian Bee," etc., and I advertised queens reared (or to be reared) in my Island apiary, where there was no possibility of their getting mixed with black bees. I am afraid that the spirit of humbuggery that was so prevalent then among hive-patentees and queen-breeders was contagious, and that I had caught it in a mild form.

As I anticipated, I greatly enjoyed the work of queen-rearing, and as I was an enthusiast on the subject, I had fair success on the comparatively slow process then in vogue; and I had orders for them, too.

But my career as a queen-breeder was soon to meet with difficulties that finally brought it to an untimely end. My Island home was an admirable place for rearing queens, but I had not given full consideration to the facilities for shipping them, and I found that an Island without steamboat communication with the rest of the world was a poor place to ship queens from promptly. It so happened, last season, that we had no steamboat connection with the States. I tried making a few shipments by sailboat to the nearest United States postoffice, but this was not satisfactory. And on this account, and other personal matters, I announced my inability to fill all orders, and returned what money I had received.

Though I did not make enough, above expenses, to pay for the two queens I had bought, I still felt well repaid for all my trouble and expense in the matter for the pleasure it gave me and the practical information gained in the natural history of the bee; I did not lose interest in the subject, and it afforded me a delightful recreation for every hour of leisure that I had, as well as honey enough for all to eat, and some to spare.

I increased my apiary until at one time I had between 50 and 60 colonies, but as I never again offered queens for sale, I have made no change in the stock in the last 30 years by introducing new Italian queens. I did, many years ago, buy a Holy Land or Syrian queen, but as I could see but little difference between them and the Italians, I did not try to keep them from mixing. I think I can now, sometimes, see in some colonies some indications of the Syrian cross, in the light-colored segments adjoining the yellow bands.

I sometimes had swarms to leave me, and they found no trouble in finding homes in the hollow trees of the heavy timbered portions of the Island, and in clearing up the land many colonies have been found, from some of which small apiaries have been started by a number of my neighbors, and they all show the three-ring test for Italians.

As I have heretofore noticed, the great contention between queen-breeders as to test of purity was the color of the queen and the markings of her progeny. These markings were found to vary even in the direct produce of the imported queens from Italy, and, in fact, were found to vary in that country. Breeders in America were therefore led to try to improve on the imported stock in regard to color, by careful selection in breeding; and they did succeed remarkably in getting brighter yellow queens than the imported ones, and, like Prof. Flanders, not only "went one better on the orthodox standard of *Three rings*," but claimed also to have queens that would produce *five-banded* workers. Not only that, but that these beautifully colored bees were more gentle and less liable to sting, etc. The importers, who had only "leather-colored" queens, with their three-banded workers, now claimed that the "improvers" had gained in beauty and color, and perhaps in gentleness, at a sacrifice of industry and other qualities that made the darker stock the better honey-gatherers. Of course this is

denied by the other side, and the controversy is still kept up to this day.

In the earlier days of the introduction and dissemination of the Italians, great stress was laid upon the claim that these new foreigners were able to get honey from flowers that the black bee could not, especially from the bloom of red clover, which, in the immense fields of it in this country "was wasting its sweetness on the desert air," that would all be saved by the Italians. There is no reliable authority that a large crop of surplus honey from the June or first bloom of red clover was ever gathered, and it is now generally admitted that too much was claimed by our ardent queen-breeders along this line. The Italians have been known to work on the second bloom or seed crop of red clover, but generally the black bees, in the same vicinity, work on it at the same time, and the largest yield from this source that I know of on record, was gathered by black bees where there were no Italians at that time. The fact is that neither race works at all times upon this second crop of red clover, and, when the bees do work on it, very little is secured in the surplus boxes. The effort now being made by certain prominent Italian queen-breeders and importers to obtain by selection and breeding a strain of Italians with longer tongues than ordinary, so that they may be able to get honey from red clover, is tantamount to an admission that the present race or strain is not able to get it—not, at least, in any appreciable or paying quantities.

Another claim of superiority of the Italians was, that they were much more prolific than the blacks, and would increase more rapidly, and swarm more frequently. Now, there is a great desire to find some way to prevent this rapid multiplication of colonies, and that claim is no particular recommendation.

It has been found necessary to keep continually trying to improve the Italian bee, or to keep them up to the best standard of their kind: First, by constant new importation from Italy; then again, by careful selections of queens for breeders of large size and full development, and whose colonies have proven the most prolific, or the best honey-gatherers; and, third, by frequent crosses of different strains from the best breeders in different parts of the country, so as to have a constant infusion of new blood. All of these means are advocated and practiced at the present time by the best queen-breeders, in order to keep the Italian bee at its best, and prove its superiority to other races.

If all this is necessary to keep the Italian bee from retrograding and to show its superiority, it is not to be wondered at that the discarded and neglected black bee stands a very poor show when compared to its much-coddled rival. I think it safe to say that no attempt has been made in this country to improve the black bee, after the manner the Italians have been improved, viz.: by foreign importations and crosses, and by queen-breeders selecting from the hardest and best honey-producing colonies. No, none of these things have been done for the black bee, and there are some who believe that, even in their neglected condition they will store more comb honey than the Italians, when both are given the same attention and management; and that they possess some valuable traits of superiority over the Italian. I will not say that in several respects the Italian is not superior to the black, but I will say that the black has never been coddled, and given an equal chance in all respects to do her best, as has her more fortunate sister.

(To be continued.)

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Uniting Colonies in the Fall.

I have more colonies of bees than I care to winter, and there is no very ready sale for them here. What is the best way to dispose of the bees and secure the honey? When is the proper time in the season for doing it?

NEW BRUNSWICK.

ANSWER.—Perhaps as good a way as any is to unite colonies. Consider to some extent the position of colonies in uniting, other things being equal uniting two colonies standing close together. A day or two before uniting kill the poorer queen of the two, and unite on the stand of the living queen. As the season is now fairly along, the uniting may be done at once, unless you are likely to have a good fall crop, in which case unite about the beginning of the fall flow.

Bees that Fought and Killed Each Other.

Yesterday (July 7) one of my colonies cast a swarm. I was at church at the time (it being Sunday), and one of the boys hived it, and left the hive where they clustered. When I came home, an hour or so later, I put the hive on the stand where I wanted it to stay. A little while afterwards I noticed quite a few bees flying where the swarm had clustered. I took an empty hive and comb and set it where the bees were flying, and in a short time I had them all on that comb—a quart or so of bees. I shook them off in front of the entrance of the swarm, and all went in nicely. Shortly after this they commenced killing each other until there were about a quart of dead bees in front of the hive. I gave them a good smoking, and they seemed to quiet down. At this writing all seems to be peaceable. What caused this fighting and killing each other?

S. DAKOTA.

ANSWER.—I don't know. It is possible that the quart or so of bees were a small second swarm, and having a virgin queen were not kindly received. Of course, all would be peaceable under that presumption after all the bees of the second swarm were killed.

Diseased Bees.

1. I put about 20 colonies of bees into winter quarters last fall, and all but one were apparently in a healthy condition, and about half of these died during the winter and spring. A large percent of the bees died in this section, some losing every bee.

My bees did not seem to build up in the spring, and about the first of June every colony had more or less dead brood. I supposed at first that the brood had died from lack of nurse-bees, as the bees that were in the hives were very old, for the reason that the fall frosts were about two weeks early, and no flow from goldenrod, so brood-rearing had stopped at least three weeks earlier than usual.

At first, scattering dead larva were seen among the brood, which were a sort of yellowish white, and very soft, but from the worst colonies no offensive odor was present, and no rosy appearance when a toothpick was withdrawn from a dead larva as described in foul brood. Some of the colonies are so bad that there is hardly a hatching bee, when all the frames are filled with brood and eggs.

About the first of May I bought five colonies of black bees for the purpose of rearing some of my best queens from colonies having only a handful of bees, and to these I introduced the queens, uniting the few bees with a frame or two they were on.

From one to a dozen of these dead larva were in the frames thus introduced. At that time I did not think this was any disease, but supposed the brood had died from starvation, as there were long-continued spells of cold, rainy weather in April and May. To-day, I find, in looking

through these hives, that dead larvæ are scattered through other frames, and one colony is bad enough to interfere with the increase of the colony. From one of my old colonies that was so bad that scarcely a bee was hatching, while all the frames were filled with brood and eggs, I removed the frames, giving empty combs, and in two days introduced a new queen, and now (about three weeks) there are no signs of disease.

How would you treat the strong colonies? Some are very strong, covering 20 Langstroth frames, and have two 28-pound supers nearly full. I have plenty of empty combs, as I run for both comb and extracted honey.

What can I do with the frames of brood and honey taken from the diseased colonies? They are all wired and built on foundation, except the five new ones, and only three of these are affected.

What do you think this disease is, that would make its appearance in every colony at once.

Do you think the weather started it, and then it became contagious? I have never known foul brood in this locality.

I have not been able to get any odor from the worst cases. When first noticed, the larvæ is about one-third grown, some looking a soft, greasy white, and some a yellowish white, and later turns brown, drying up in the cell—some curled up and some lying lengthwise.

2. Do you think these combs can be used another year by placing them under water in a current?

MASSACHUSETTS.

ANSWERS.—I'm afraid there is disease among your bees, which, although now apparently overcome while the honey-flow is on, will reappear in the future. In the meantime it will be advisable for you to get all the literature you can on the subject, especially the leaflet on pickled brood, and back numbers of this journal relating to diseases of bees, and being thus informed upon the subject you can form a better judgment of the case than can one at a distance.

2. Placing diseased combs under running water would not be likely to do any good.

Storing in the Brood-Nest—Swarming Out.

1. In the months of November and December here the queen greatly diminished her egg-laying, and the bees filled up nearly every comb with honey. If extracted, the bees stored in honey all the same, and very little brood would be kept up. This greatly reduces the force of the colony. What must I do to prevent the bees storing honey in the brood-nest in such season of the year?

2. When my colonies swarm I destroy all queen-cells and turn back the swarm (with the exception of the queen, which I give to some queenless colony). A few days after I destroy the remaining cells, such colonies now being left without queen or cells. About two weeks after I give them a cell each: every one of the colonies swarmed out with the virgin queen. What must I do to prevent such swarming?

JAMAICA.

ANSWERS.—1. It is not easy to prevent the bees from filling the combs with honey in some cases. Having young queens will help. If you give empty frames or foundation it will give the queen a better chance to get in her work.

2. Instead of destroying all cells and then giving another cell two weeks later, if you leave one cell—or if you want to give a cell from choice stock give it at the same time you kill the cells—you will not be likely to have so much trouble with the bees swarming out. With your present plan there is no brood, or at the most a very little sealed brood, in the hive, and when the queen goes out on her wedding-trip the bees go along.

Bait-Sections—Extracting, Etc.

1. I have the Ideal super and sections; some have been on my five hives over two months, but the bees have not yet worked in them at all. The frames are irregularly filled, average two-thirds; 8-frame hives. The books say bait with old or used section-boxes, but I am a beginner, and have only the one kind new. I can borrow 4½ x 1½, but they are no fit, if that makes any difference to bees.

2. How can I extract honey from comb without an extractor? It could not always have been done with those machines. I scrape out the honey and comb together with a tablespoon, on each side of the foundation, cut it into a

dish or pan, and separate it as we eat it. I want to put it into jars.

3. By the way, the foundation goes to pieces in scraping, though I use great care; some breaks in carrying to the house, about 20 steps. I use what is called in catalogs "medium brood foundation." I am told it ought to remain good in the frame at least eight years. CALIFORNIA.

ANSWERS.—1. So long as the brood-frames do not average being more than two-thirds filled, you hardly ought to expect bees to do much in sections. Indeed, without any bait in supers you ought not to expect them to make any start at all until the brood-chamber is filled, and even with bait they will confine their attention in the super to the bait alone until they have more honey than they can get into the brood-chamber. You need not be thwarted in the matter of bait because you have no partly filled sections of the right size on hand. If you can get sections of another size, cut out the comb and fasten it into one of your sections. You may even cut a piece of comb with brood in it out of a brood-frame and fasten it in a section for bait. It will not make a desirable section when completed, but nothing can be more seductive to the bees in the way of bait.

2. I don't know of any way by which you can get honey out of a comb without an extractor that will leave the comb intact, unless it be to let the bees empty it.

If I understand you rightly, when you are scraping the honey away from the septum the latter gives way. Foundation may become dry and brittle through age, but after such foundation is put in use by the bees I doubt its being specially different from other. It is probably not so much brittleness as tenderness of which you complain, and the freshest foundation would have the same fault, the natural comb being still worse.

Honey-Plant Questions.

1. Is yellow sweet clover better than white for bees?
2. Is crimson clover good for bees? Does it bloom the first year?

3. When is the best time to sow either?

4. Does cleome bloom the first year? If so, about what time of the year does it bloom? SUBSCRIBER.

ANSWER.—1. I don't know. Although I have sowed some this year it can not blossom before next year, and there is such a terrible drouth that none of it may be alive. It would be of interest if the readers of this journal, who have had both white and yellow sweet clover, would give us some idea of their relative merits.

2. It is a fine honey-plant. It is usually sown late in summer, blooming the next season before white or red clover. If sown early in spring, some of it may blossom the same season.

3. Sow sweet clover about the time of sowing oats in spring; crimson clover in August. Sweet clover may also be sown in the early fall.

4. Cleome integrifolia, or Rocky Mountain bee-plant, if I am not mistaken, blooms the first year toward the latter part of summer.

Cleaning a Mice-Infested Hive.

Can a hive be cleaned that has been infested with mice? If so, how? WISCONSIN.

ANSWER.—If you mean the combs, the bees will clean them up. If the hive without combs, use soap-suds.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

THE BABY.

What is the little one thinking about ?
Very wonderful things, no doubt,
Yet he laughs and cries, and eats and drinks,
And chuckles and crows, and nods and winks
As if his head were so full of kinks
And curious riddles as any sphinx !
Warped by colic and wet by tears,
Punctured by pins, and tortured by fears,
Our little nephew will lose two years ;
And he'll never know
Where the summers go.
He needn't laugh for he'll find it so !

This is from the genial pen of that wholesome writer, Dr. J. G. Holland. I would have his books grace the table of all our home circles. "Boy Path" and his other stories are always inspiring, and inspire our young people to pure thought and purpose. The poem from which the above is taken is so full of humor, of unflagging interest, of real philosophy, that all our children and young people may well read—the children portions of it, and the older ones all of it. Like Job, it discusses the problem of evil, and will help to get a philosophy of life and thought that can not come too early into the heart and life.

I hope all our mothers will see that "Bitter Sweet" is among the volumes that the children prize as among their best belongings. Then side by side have "Kathrina" and "Timothy Titcomb's Letters to Young People"—all by the same author. All are good to read with the children ; all will develop in pure wholesome lines ; all will invigorate, and give a start-off from a right, true foundation.

But we have almost forgotten the baby. Luther said he loved and felt awed before the baby. For in every baby is the promise of so much of good or evil. Every infant is potentially so pure, true and noble, or so base, depraved, and ignoble, that no wonder we are alert at the very cradle to start the little craft in best courses, that baby, mind and soul, may all trend towards the fairest port. The poem further traces the little craft—

Out from the shore of the great unknown,
Blind and walling, and alone,
Into the light of day,
Out from the shore of the unknown sea,
Tossing in pitiful agony,
Of the unknown sea that reels and rolls,
Specked with the barks of little souls—
Barks that were launched on the other side,
And slipped from heaven on an ebbing tide.

And how beautiful this reference to the mother :

What does he think when her quick embrace
Presses his hand and buries his face,
Deep where the heart-throbs sink and swell,
With a tenderness she can never tell,
Though she murmurs the words
Of all the birds—
Words she has learned to murmur well.

We have seen that influences towards truth-telling, self-control, unselfishness—the blessed trio of human virtues—must push for a hearing at the very cradle. The sad experience of the last few days of heated summer weather, in thousands of our American homes—experiences which force their unwelcome presence—to darken the lives and hearts of bereaved parents over and over with the years, shows that the slender, delicate little bodies, even more than the mind and soul, need a first thought in these early, fragile months. So many of the little souls that fleck the sea of infancy flounder and are lost to all influence and usefulness in the world.

The baby is full of most sensitive nerves. Every one of these seems to reach to the surface, each seems tied to the other. If one is pinched, all cringe. So ready and active is this sympathy, that a toothpick or a lurch which the digested machinery fails to reach, brings the spasm, or the fatal bowel complaint. Almost before we know it the little craft sinks beneath the waters, and we are left hopeless to mourn our terrible loss.

The very functional sympathy just referred to makes infancy the critical stage of life, and explains the mortality which is so startling at this period. Paul's words are now emphatically and peculiarly true. If one member suffers, all the members suffer with it. A fall from a chair, which one older would scarce notice, brings the spasm, and, mayhaps, death; the cutting tooth, which with years would scarce prove a pinprick, now blocks the stomach and brings the fatal bowel complaint. A change of food that later would come with relish, now smother's digestion and blows out the life-light. The excitement of too many attentions from admiring friends, which with more of age would be all invigorating and life-giving, now wearsies till the energies flag, and the bodily functions, tired out, cease their action.

We must ever remember that infancy is the critical age; that the very sympathy between the organs is a menace to life itself. Teething, which comes at its worst phase at about the first year-mark, is ever to be dreaded. The heat of summer is full of menace. Change of place and companions at this susceptible age is too stimulating, and fraught with danger. Change of food is often the very last straw, and the back severs. Combine all these, and what wonder that the fragile little craft goes to the bottom ?

It may be wise to leave home in summer. This is vacation time. But if a baby adorns our home and gladdens our arms, we better think twice, especially if at about the year, date when the great molar is trying to push through. Then if we must go, we must seek a cooler place, a quiet nook, and plan that there be no change in the food. Often the plunge is from country to city, to the dear old home friends, who rightly appreciate the little walf as a very treasure, and thus keep it waked and going till excitement and exhaustion have done their work. Usually the food is changed perforce, and with the heat, excitement, change, enforced by the off-ending molar, the foe is too numerous and strong, and the struggle very brief. The wise, thoughtful parents will see that the little jewel which gives charm to the home and life is too rare and precious to permit even vacation pleasure and change to bring threatening dangers. They will forego even the visit to the old home for baby's sake. They will plan with all the astuteness of love to minimize the dangers that menace infancy, and will gladly forego the change or visit—even the rare, gracious pleasure of re-living the gladsome life of the old home, for the sake of the life and health of the blessed baby.

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers one ounce of the seed for sending us ONE NEW subscriber to the American Bee Journal for a year with \$1.00; or will mail to any one an ounce of the seed and the American Bee Journal one year—both for \$1.30; or will mail an ounce of the seed alone for 50 cents. As our stock of this seed is very small, better order soon.

Standard Belgian Hare Book!

BY M. D. CAPPS.

This book of 175 pages presents a clear and concise treatment of the Belgian Hare industry; its growth, origin and kinds; the sanitation and construction of the rabbitry; selection of breeding stock; care of the young, feeding, diseases and their cures, scoring, marketing, shipping, etc. First edition of 20,000 copies was sold in advance of publication.

Price, in handsome paper cover, 25 cents, post-paid; or with the American Bee Journal one year—both for only \$1.40.

ADVERTISEMENT.

To Our Shippers :

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "HILDRETH, McCaul Co.," and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name HILDRETH in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract :

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120 122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs: it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are hereby restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the defendant at No. 120 122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of "Hildreth" separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDRETH & SEGELKEN,

265-267 Greenwich Street, NEW YORK, N. Y.

QUEENS

QUIRIN THE QUEEN-BREEDER has now on hand, ready to mail, **500 young, long-tongued Red Clover Queens, Golden or Leather Colored.**

We have one of Root's best breeders from his **52nd, long-tongued, Red Clover Queen, and a Golden Breeder** which we are told is worth \$100, if there is a queen in the U. S. worth that sum.

J. L. Gandry, of Humboldt, Neb., tells us that the colony having one of our queens, stored over 400 pounds mostly comb honey in a single season. A. I. Root's folks say that our queens are extra fine, while the editor of the American Bee Journal tells us that he has good reports from our stock from time to time.

We have years of experience in mailing and rearing Queens. Queens positively by return mail from now on. Prices for balance of season as follows:

	1	6	12
Selected	\$.75	\$ 4.00	\$ 7.00
Tested	1.00	5.00	9.00
Selected tested	1.50	8.00	
Extra selected tested, the best that money can buy,	3.00

cells will surely be found here. In fact, if the frames are well filled with combs, as they usually are in this hive, queen-cells are rarely found in other parts of the hive.

When the season and weather conditions are favorable for swarming, we look in this bee-space. If there are queen-cells that show eggs only, we mash them down and close the hive. That colony is safe for another week. If there are queen-cells containing larvae, we proceed to divide the colony at once. A few vigorous pulls of smoke into the top of the brood-chamber will usually drive the queen into the lower part of the hive. We place this part of the hive at one side, with its entrance facing at right angles to the old stand. On the old stand place the balance of the brood-chamber on another hive-bottom, putting a case of empty combs, foundation, or starters under each part of the divided colony. Divide the surplus-cases between the two hives, and give more surplus-room if it seems necessary. Treat each colony in the yard that is likely to swarm in the same way.

If convenient to look at the hives just before dark, it is easy to tell where the queens are. The queenless bees will be uneasy, and crawling about the front of the hive, apparently hunting for their queen. If it should appear that she is in the part of a colony left on the old stand, exchange places with the removed part. By morning the queenlessness will not be so apparent. It is better to have the queen removed from the former stand, as most of the field-bees will return to the old home, although this is not really essential. The weakening of the colonies, and the additional room given will almost always cure them of the swarming fever.

At the next examination, a week later, it will be easy to determine in which part of the divided colony the queen is, by the eggs in the brood-cases. Place all the surplus-cases, and the hive that has the queen, on the old stand, and put the queenless brood and a few bees in a hive at one side. This small colony may be used for strengthening a weak colony, as a nucleus for queen-rearing, for increase of colonies, or as a surplus case on any hive in the yard.

Bait-Sections.

I was glad to see Mr. Doolittle standing up so staunchly for these. Several eminent bee-keepers some time ago contended that they were fit only for being smashed up and made into wax. I would have every single unfinished section carefully preserved, and one placed in the center of every super. But I would have them all nicely cleaned up by the bees before storing them away, as I fear any granulated honey they might contain would be a source of "infection," and granulate the new crop stored in them. This seems to be a moot point, however. I "blundered" all these sections, and seldom find that they show any defects of construction or finish. British Bee Journal.

Prolong Lives of Best Queens.

SAYR Stray Straw in Glennings in Bee-Culture:

Longevity in bees is coming to the front. Assuming that in harvest time a worker lives six weeks, and goes ahead when 16 days old, if its life were prolonged a week it could store 27 percent more. If one queen lives twice as long as another, will not her workers live at least a little longer? Is it not possible that, by proper selection continuously exercised, we might add that week to the life of the worker? If we could add a sixth to its summer life, that ought to add 3, sixth to its winter life. In that case, a bee born Oct. 1, which now lives till April 1, would live till May 1—quite a help in the wintering problem. Another thing: We can tell better what a queen is by two or three seasons' work than we can by a single season's work. The one that shows herself best for three seasons is a safe one to breed from. I have a queen born in 1887 that are among the best—one of them, I think, the very best I have. While this is true, the average queen, I think, would better be displaced in two years by a young one.—Editor

THE MODERN FARMER & BUSY BEE.

EMERSON TAYLOR ABBOTT, Editor.

A live, up-to-date Farm Journal with a General Farm Department, Dairy, Horticulture, Livestock, Poultry, Bees, Veterinary, Home and General News. Edited by one who has had practical experience in every department of farm work. To introduce the paper to new readers, it will be sent for a short time to New Subscribers, one year for 25 cents. Sample copies free. Best Advertising Medium in the Central West. Address.

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the Ameri-

can Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

QUEENS! QUEENS!

From honey-gathering stock. Tested, \$1.00; untested, 75 cents. "SHADY NOOK APIARY." **JAMES WARREN SHERMAN,** 29 ALBION, SAG HARBOR, NEW YORK.

Mulberries and Bees.

It may not have occurred to some of your readers that a remarkable honey-plant they may have, right at their doors, irrespective of locality.

In the coldest habitable region the white or Russian mulberry may be depended to thrive. In the heat of the South it flourishes and supplies abundant shade. In the more temperate climate of the East it spreads its long limbs, like an eagle poised in flight. In the barren sands of the extreme West its glossy foliage revives hope as does the date-plant in the Sahara Desert, yielding abundant fruit after the fifth year.

It is so easy of cultivation that no one need fear failure. It is easily propagated from seed, and cuttings take root in moist soil as readily as willows, attaining a height of from 60 to 100 feet, and girth of trunk from one to two feet in diameter. Planted a foot or two apart it affords an attractive hedge-fence, as effective as the osage orange.

The availability of the mulberry for shade, post-timber, and fire-wood, must appeal to all sensible farmers. Though a comparatively soft wood, it is of tough fiber, successfully resisting the force of the winds when less yielding trees break off. Its far-reaching roots are great foragers for this tree's sustenance and anchorage. The fruit is a creamy-white, and so sweet (87 percent saccharine) that one must acquire a taste for its enjoyment. Not least of its virtues is the ease of its harvest. Simply spread a sheet under the tree and shake well to bring its luscious fruit. No sugar is required for their preparation for the table. Milk or cream greatly improve their delicacy. Made into jam, no fruit is healthier, more cheaply prepared, nutritious, or more relished by young or old who are fond of natural sweets. I can only liken the berry to a vegetable honey, so pure its flavor and agreeable its sweetness.

To touch upon the economic value of mulberry leaves in fostering the culture of silk industries is ancient history. The Egyptians, the old Greeks, the Romans and their descendants have profited through careful attention to this vegetable loom of Nature.

I intend simply to suggest as a result of my personal experience, that its ripe berries are eagerly pounced upon by the bees as they would a broken comb of honey. The manner of feeding is exceedingly simple. I crush the ripe white mulberries in any convenient dish, and with a piece of single, large spoon, or any light carrier readily at hand, I place a quantity of the berry-pulp upon their alighting-board. The bees will naturally investigate for some moments, but when they have tasted the sweet juices a very crazy seems to possess them to completely cover the mass, and extract every vestige of its sweetness.

It is possible that, here we may glean a hint that will, in great measure, forestall the almost complete honey failure of the last few years, and bring our industry back into the channels of success and profit.

(Cook Co., Ill. Dr. PERRO.

[The Doctor brought to us a sample of the mulberries, and we fed it to our bees after crushing. Well, they just carried it in sick and clean from the alighting-board in double-quick time. We should like, to taste the flavor of the honey produced from mulberries. —EDITOR.]

A Swarming Experience.

I do not know that I can give the explanation asked by Dr. C. C. Miller, on page 124, in any better way than to give a part of my swarming record for this year.

Swarms issued: No. 23, May 30, hived in No. 15; No. 15, June 30; No. 24, July 7.

You will see by this, that my new or prime swarms cast a swarm as rich of my new or prime swarms do, and that the parent colony.

A Superior Red Clover Queen

(AN UNTESTED ITALIAN)

For sending us One New Subscriber and 25 cents (\$1.25 in all.)

We arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us this season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he uses is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

We would like each of our present readers to have one or more of these fine Queens. Simply send us the name and address of a new subscriber for the American Bee Journal for one year, and 25 cents extra, and the Queen will be mailed to you. Our queen-rearers is now caught up with orders, and expects to be able to mail them hereafter, within 48 hours after we receive the order. He is in another State, and we will send him the Queen orders as fast as we get them at this office. He is prepared to rear and mail a large number.

The cash prices of these Queens are \$1.00 each; 3 for \$2.70; or 6 for \$5.00.
Send all orders to

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

after getting a young laying queen, cast a swarm 39 days after throwing off the prime swarm. This is the quickest that I ever had. It is usually between six and eight weeks, and a common occurrence with my bees; and swarming is not their only motive, as I am getting lots of honey. I think I am in an exceptional locality. I came here from the southern part of this State, and bees never swarmed that way there, so my knowledge at least.

Kanabe Co., Minn., July 12.

Bees Doing Fine—Alfalfa.

Bees are doing fine. I send a sample of honey. Please let me know what it was gathered from, as we are unable to find out where the bees go. I think they must go a long distance. I rather think it is alfalfa honey, as the farmers are beginning to sow it here some. The bees are busy from early morning until late, and seem to be the only ones that are not complaining of the heat and drought. The temperature has been from 98 to 102, the last two weeks.

Mrs. W. S. YEATON.

Woodbury Co., Iowa, July 20.

[The sample of honey has the color and flavor of alfalfa. It is very fine. Get all you can like it, as such honey never need wait long for a buyer.—EDITOR.]

Good White Clover Flow.

The white clover honey-flow has been unusually good, but is probably at an end. From 35 colonies, spring count, and an increase of 20, I have harvested 818 sections, and there are on the hives some 2000 sections, most of which are full, besides some half dozen extracting supers full. I have several colonies that have produced upward of 150 sections, and three or four have done still better than that.

F. W. HALL.

Sioux Co., Iowa, July 22.

Too Hot and Too Dry.

We are suffering with heat and drought here. I had 21 colonies of bees, spring count, and have 30 at present in fine condition. My crop of white honey will not exceed 400 pounds, and there is no sign of rain, consequently we can not expect a fall crop; but I must have my American Bee Journal.

Mrs. PAUL BARRETTE.

Crawford Co., Wis., July 19.

Another Honey Crop Failure.

I am sorry to have to report another failure of the honey crop. It seems as if there would be nothing this fall, either. In the way of honey for our fields are parched. The corn is tasseling out without any prospect of ears, and the crop of weeds, which are generally luxuriant at this season, seem to be just as bad off as the more valuable plants. This is probably one of the worst droughts ever seen in this section.

C. P. DADANT.

Hamilton Co., Ill., July 19.

Hot, Dry Weather.

We had a good start of white clover honey, but the hot, dry weather has nearly finished the flow. Basswood yielded but little, and as it is so very dry but little can be expected from heartsease and buckwheat.

Linn Co., Iowa, July 13. G. H. FREY.

Don't Report Glowingly or Too Soon.

There is a report from this county (Marshall), in a recent number of the American Bee Journal, from J. W. Sanders. He says that we are having the heaviest crop we ever had in the State. Now, I have not found it so. We had a few days that were extra good, but the dry weather and strong, southwest wind killed the clover, and made what little basswood bloom there was barren of nectar. I consider that my crop was cut one-half from

Please Mention the Bee Journal when writing Advertisers

what it would have been, if we could have had 10 days more of the right kind of weather. I think bee-keepers should be very careful not to give too glowing a report, and not report too soon.

I put 42 colonies into the cellar last fall, and took out 49 good ones. I have increased to 63. I will have about 50 pounds to the colony, spring count; about one-fourth extracted, and the balance comb honey.

C. P. Mc KINSON.

Marshall Co., Iowa, July 20.

Too Wet for a Honey Crop.

On account of too much rain there has been no honey taken in this locality yet. White clover, Linden, and chestnut are in full bloom, and bees work nicely when the weather is fair. All my colonies are very strong, and in good condition to work, but so far no honey.

S. F. SAMPSON.

Greenbrier Co., W. Va., July 17.

Bees that Have a Record

(See page 459 American Bee Journal.)

Have longest tongues, handsome, gentle, great hustlers for honey, all tested genes, and sold at rate of \$8 per dozen. By return mail.

—THE—

Bee-Keeper's Guide

Or, Manual of the Apianry.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co.

Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—This nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apianry, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains full description of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accordance with nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey," 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding, 100 pages, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

Please mention Bee Journal when writing.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 18.—Choice white comb honey is arriving rather more freely and brings 15c. There is no accumulation at this writing, so receipts sell within a week after arriving. Some of them on the same day. Amber grades bring about 12c. Extracted dull and slow sale at anything over 7 1/2 c. Beeswax steady at 3c with good demand. R. A. BURNETT & Co.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from 1/2 to 1 cent per pound. C. H. W. WERER.

BOSTON, June 23.—There is practically no comb honey in our market and owing to wet weather very little call for it. Are expecting some new comb early next month. Market for extracted dull, at 1/2 to 7/8 c. BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00. PEYCKER BROS.

NEW YORK, July 8.—Our market is practically bare of comb honey, and demand good for white comb. Fancy stock sells readily at 15c; No. 1 white at from 13 1/2 c, and amber at 11 1/2 c. Extracted not in much demand, with plenty of supply; white, 6 1/2 c; light amber, 5 1/2 c; dark, 4 1/2 c. Beeswax firm at 2 1/2 c. HILDRETH & SEGELKEN.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts or stocks and little demand. It is between seasons now. Prospect of good crop in this vicinity from which bees there are left, the greater portion having been killed by foul brood exterminators. H. R. WRIGHT.

DETROIT, July 18.—Fancy white, 15c; No. 1, 13 1/2 c; No. 2, 12 c; dark, to quote. Extracted, white, 6 1/2 c; dark and amber, 5 1/2 c. Beeswax, 2 1/2 c. M. H. HUNT & SON.

BUFFALO, July 10.—No demand for honey yet unless a very small amount of fancy white at perhaps 15 1/2 c. Some old lots still about, unsalable, almost, at 6, 8 and 10 cents. Beeswax, 2 1/2 c. BATTERSON & Co.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being granulated. Sales are light at 15 cents for best grade No. 1 Colorado. Amber, 13c. Beeswax firm at 2 1/2 c. W. R. CROMWELL PRODUCE CO. Successors to C. C. Clemens & Co.

SAN FRANCISCO, June 19.—White comb, 11 1/2 c; 12 1/2 c; amber, 10 1/2 c; dark, 6 1/2 c. Extracted, white, 5 1/2 c; 6 1/2 c; light amber, 4 1/2 c; amber, 3 1/2 c. Beeswax, 2 1/2 c.

Market shows no quotable improvement, but there are no large quantities obtainable at the prices generally named by dealers. In a small way, for especially desirable quantities, slightly higher prices than are quoted are being realized.

More Bee-Keepers' Paradises....

E. R. Root has just returned from a 6,000-mile trip through some of the best bee-locations in the world, and has already begun his series of write-ups, accompanied with fine photos, in Gleanings in Bee-Culture. The following editorial appears Aug. 1, and will give something of an idea of what he will describe:

Some little time ago I promised to tell about the bee-keepers' paradise in Texas. I have this on the docket, and it will appear as I take up the line of my travels. But since running across that paradise I have run into two or three others. There is one west of the Rockies, in Colorado, that is not yet overstocked with bees or bee-keepers; another one in Central Idaho—in fact, I do not know but the whole State. These will be described in turn. The fact is, millions of capital are being invested in irrigation; irrigation means alfalfa; alfalfa means a paradise for bees. But I found all along my trip that alfalfa-growing preceded bee-keeping by two or three years, for it seems to take about that length of time before bee-keepers find these gold-mines that have been hitherto unoccupied.

If you are dissatisfied with your present location, and for financial reasons, or on account of health, will be compelled to leave, subscribe for Gleanings in Bee-Culture, and learn something about the great South and the great West. There are many locations in the West that are not yet occupied—splendid bee-locations. If you wish to learn about them, send 25 cents for a six-months' trial subscription, or \$1.00 for one year and one untested Italian queen. Or, send \$2.00, and we will send Gleanings one year and one of our celebrated Red Clover Queens.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

A Superior Red Clover Queen

AN UNTESTED ITALIAN!

For sending us One New Subscriber and 25 cents (\$1.25 in all).

We arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us this season. His bees average quite a good deal the longest tongues of any yet measured. The breeder he uses is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

We would like each of our present readers to have one or more of these fine Queens. Simply send us the name and address of a new subscriber for the American Bee Journal for one year, and 25 cents extra, and the Queen will be mailed to you. Our queen-rearers are now caught up with orders, and expects to be able to mail them hereafter within 48 hours after we receive the order. He is in another State and we will send him the Queen orders as fast as we get them at this office. He is prepared to rear and mail a large number.

The cash prices of these Queens are \$1.00 each; 3 for \$2.70; or 6 for \$5.00.

Send all orders to

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

Queen-Clipping Device Free....

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,

GEORGE W. YORK & COMPANY,
Chicago, Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of german silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a long time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it, but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelty" knives, your POCKET KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to one sending us THREE NEW SUBSCRIBERS to the Bee Journal [with \$3.00]. We will club the Novelty Knife and the Bee Journal for one year, both for \$1.00.

GEORGE W. YORK & CO.

St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

No. 32.

* Editorial. *

General vs. Special Knowledge.—The tendency nowadays is toward specialism. Even in bee-keeping there are special lines, and a man is likely to do his best when he confines himself within certain limits. But it is a serious mistake to think that one should study up only what comes directly within his line. It is not likely that any bee-keeper became very proficient in any one line without being pretty well informed in all other lines pertaining to bee-keeping. A good, all-around bee-keeper makes the best basis for a good specialist. Dr. Miller's advice in another column is good. Inform yourself in advance, even upon subjects that you think may never have any interest for you. Study *all* of your text-book until it is familiar. Don't omit a knowledge of the Dzierzon theory. Lay a solid foundation, and then when the time comes that knowledge upon any point is needed, it will be ready.

Northern vs. Southern Queens.—A wordy discussion upon this subject occurs in the Southland Queen between S. E. Miller and E. J. Atchley, which, if it proves nothing else, proves that men may have very different views. What one claims for the North the other claims for the South. Mr. Miller claims that people of a temperate climate are superior to those of a tropical climate in strength, hardiness, industry, and otherwise, and that where a Northern and a Southern army meet on equal terms the Northern army is victorious. Mr. Atchley says late history proves that it takes ten Northern men to conquer one Southern man; that the men and women of the South, as a rule, are strong and robust, capable of enduring great hardships, and less subject to disease than those of the North, that Southern queens lay more and live longer, and the bees live longer, are more hardy, and rather more honey.

Feeding Back.—Editor Hutchinson is one of the limited number who has made a success of getting sections completed by feeding back. In the Bee-Keepers' Review he gives some excellent hints. If the feeding is begun just as the flow from basswood is beginning to slack up, the work will go on apace, whereas every day's delay after that time will make it necessary for the bees to fill up again in the brood-chamber. Contract to five Langstroth combs at the most. Three

are better, but in that case there will be a weakened colony unless it is strengthened by adding to it cases of sections, bees and all, from other colonies. Add boiling water to the honey to be fed until it is thin as nectar. With 100 pounds of unfinished sections and 100 pounds of extracted honey, Mr. Hutchinson gets 160 pounds of finished sections. He says further:

Black bees do the best work; hybrids next; then comes the dark Italians. Light Italians do very poor work in feeding back.

Sort over the sections, making two grades of them as regards their completion. Contract the brood-nests of the colonies that are to be employed. Set the cases of sections around, one on a hive, but not on the hives containing the colonies that are to be employed in feeding back. The bees will go up and occupy the sections. Now gather up the cases, bees and all, and put two cases on each hive. This is done to secure populous colonies, as they do the best work in feeding back. I have never had trouble from the bees quarreling. Put a case of nearly finished sections next to the brood-nest, and those that are not so nearly finished on top, and then the feeder.

Note the peculiarities of the different colonies. One will take down the feed and draw out the combs much better than will some of the others. Another colony will be a poor "feeder," but will cap the honey much better than some other colonies will cap their honey. As the work progresses, and fewer colonies are needed, throw out those that do the poorest work.

A Putty-Knife as a Hive-Tool. to scrape propolis off the hives, pry frames apart with, and for scraping off burr-combs, is recommended in the Progressive Bee-Keeper. "Sonnambulist" suggests that a small trowel with the edges sharpened is hard to beat.

Moving Bees for Fall Flow.—An interesting discussion upon this topic at the Ontario convention is reported in the Canadian Bee Journal. Among the points brought out was one that even if no surplus is gained there may be pay for the trouble in the better supply of winter stores, and still further there may be a great advantage in the greater number of young bees to go into winter quarters. It was urged that, although for spring and fall moving a large-sized entrance covered with wire-cloth may give sufficient ventilation, this will not do when moving to the buckwheat fields in hot weather. There should be a space of two inches over the brood-frames, with wire-cloth over. Some preferred a hay rack with a layer of hay without springs; others preferred heavy springs. A board platform may be used with common carpet tacks sprinkled over it. The tacks will sink into the platform and into the hive-bottoms, preventing the hives from sliding about.

To prevent trouble with a nervous driver in

case any hives should spring a leak, mosquito net may cover the entire load. On a clear, warm day, if bees begin to stick their tongues up through the wire-cloth, they should be well sprinkled with water. The bees will suffer less if hauled at night, or if the start be made in the middle of the night. Frames should run cross-wise on the wagon. Some hauled the bees home late in the fall, putting them immediately in the cellar without opportunity for a flight, and found no bad results.

Albatta Honey, although always of good flavor, says Editor Root, varies in color, in some localities being light amber, and in others almost water-white.

Measuring Bees' Tongues.—It has more than once been suggested that it is no safe criterion to judge the value of a worker-bee by mere length of tongue alone, because there may be a difference in the energy of two bees having tongues of the same length. This difference can be measured by the difference in the amount of stores gathered by two colonies. A. J. Wright, in *Gleanings in Bee-Culture*, proposes a more expeditious method of measuring this energy, and without taking all the bees of a colony. He has constructed an ingenious glossometer, which gives measurements to the thousandth of an inch, and says:

"The energy of the bees is clearly shown in their efforts to reach the candy. While some are easily discouraged, and give up without much effort, others will persevere, and work and stretch their tongues to the utmost limit; and when the candy is clearly beyond their reach they seem loath to yield."

Mr. Wright is perhaps the first to suggest the advisability of measuring the capacity of the honey-sacs of different bees, in doing which only one bee must be taken at a time and allowed to fill its sac from a receptacle so small that the amount taken can be accurately determined. While in general larger honey-sacs go with longer tongues, two bees having tongues of the same length may have honey-sacs of different capacities. It is not hard to believe that a bee with a small honey-sac must make more journeys, hence consume more time, in storing a given amount, than one with a larger sac. He says that the flying bee, when reaching for nectar, can protrude its tongue further than the tongue of the dead bee can be stretched without rupture, and that the bees of a queen, if purifier but little from each other in tongue measure, capacity of the honey-sac, or working energy. Objection is made to using wire-cloth in a glossometer, as the apertures are by no means uniform in size or shape.

Width of Top-Bars of Extracting-Frames, Etc.

BY C. P. DADANT.

MR. DADANT:—I would be very much obliged to hear from you as to what width of top-bars you would advise to use when only 9 frames are used on a ten-frame hive? Then another question: Which do you consider the best way to have combs in extracting hives cleaned by the bees when they are not to be used again the same season? We have sometimes put such extracting hives back on the colonies, but frequently a good many bees remained in them, and again at other times they gathered the honey all right but did not take it down in the brood-chamber.—JACOB WAGNER.

In replying to these questions, I will refer the reader to an article previously written by me on page 452, on the spacing of extracting-frames, and the number of them to be used in the super.

The thickness and width of top-bars has influence, in only one particular, as far as I know, that is, it helps control the amount of burr or brace combs built by the bees. With a light top-bar, of narrow width, the bees will often build a great number of brace-combs, joining one comb with the other and filling every available space with honey. This makes the handling of the combs more or less inconvenient. When the frames are made with a wide top-bar, leaving only a narrow bee-space between the combs, and especially when the top-bar is also thick perpendicularly, there is much less brace-comb built.

But, in extracting, the wide top-bars have the great inconvenience of being in the way of the uncapping-knife, until the combs are built out far enough to remedy this. Many of our friends prefer the ordinary narrow triangular top-bar for this very reason. In our own practice, we have used both the 1½" top-bar and the 2", and we find very little difference in practical results. If the frames are kept as far apart as is necessary to secure thick combs, the bees will build brace-combs anyhow, even if we use wide and thick top-bars. But we do not find much inconvenience resulting from it, because we keep our bees sufficiently supplied with space to prevent them from building brace-combs. The latter are usually built when space is getting short in the super and seem to be the finishing touch which the bees give to their supers. If we forestall their aim, by adding more combs or by extracting, no brace-combs will be built. So, in our estimation, the width and thickness of the top-bar of extracting-combs is not of any particular importance.

CLEANING EXTRACTING-COMBS.

Concerning the giving back of the extracted combs to the bees to be cleaned at the end of the season, I am decidedly in favor of the affirmative. The question was discussed at length last spring in the International Review of Bee-Culture, of Switzerland. My readers well know that, over there, they produce extracted honey almost exclusively, and many different methods are followed. There seems to be about an equal division on the matter of returning the combs to the hives. But the advantages of the method, in my mind, very greatly overbalance the disadvantages.

It is held by those who are in favor of not returning the combs to the hives, that they are just as easily kept when sticky with honey; that it saves a great deal of time, and quite a great deal of trouble, and that when the supers are given to the bees in the spring, they work in them much more readily if these combs are rendered attractive by the honey sticking to them.

On the other hand, the combs which are left smeared with honey when put away for winter attract mice much more readily than if they have been thoroughly cleansed by the bees. Mice will make very little effort to enter a surplus case, if there is no smell but that of the wax; but if they can perceive the odor of honey they will take special pains to work their way in, for they are very fond of it. Whenever I have had combs damaged by the mice, I have almost invariably found them to be combs that contained honey, especially honey that was strong in flavor and odor.

Another objection is, that when you put the supers on the hives, in spring, you run the risk of exciting the bees to rob, for it is very often before the opening of the crop that the supers are put on the hives. It is true, the same

precaution might be taken in the spring to put the supers on the hives as is taken to return them to the bees in the fall, by doing it at the end of the day's work, just before night, so that any excitement caused by the running honey will soon be quenched by the shadows of night. But it is much easier to do this after a day's extracting when you have a force of four or five people on the spot, than to do it in the spring, when the apiarist is usually alone to do the work.

There is also another objection to leaving all the combs daubed with honey for four or five months—it is the danger of causing a fermentation in this honey. We all know that honey has a strong tendency to the absorption of moisture—it then becomes watery, and ferments easily. When it is spread over a considerable area, as is the case after extracting, there is a very great danger of this fermentation, and though the quantity is very insignificant, it produces numerous germs on the combs which are to contain the next crop, and it seems to me that there is but little doubt of the danger arising from this for the following harvest, especially if the honey was watery when gathered.

It is true that it takes a little more labor to put the supers back on the hive, when we know that they must be again taken off before winter, but it is thus with every pursuit—we can have nothing without labor, and those who take the most pains are usually those who succeed best.

Hamilton Co., Ill.

Long-Tongued Bees—A General Rejoinder.

BY G. M. DOOLITTLE.

MY article on long-tongued bees, on page 293, seems to have stirred them up quite generally, if what has appeared in print on this subject since then gives a true indication in the matter. And I have waited a little, till "the storm had passed away," so that I might send in a general reply to all, for I see that I did not make myself fully understood in my former article. Some seem to get the impression that I was accusing *advertisers* of making "false statements" regarding long-tongued bees, for the sake of gain. I did not intend so to do. What I did intend was this:

Gleanings in Bee-Culture, through "Stenog," said, "The movement for longer tongues is simply to get the red clover crop of the North, which now is practically all wasted. The bees, no one claims, would be any better except on that account;" while in the same number of Gleanings were advertisements stating that long-tongued bees were better for all parts of the country, red clover or no red clover, or at least with no qualifications regarding the red clover matter. And as these statements were directly opposite, I wished to show that one or the other was, and must of necessity be, "actually false." If this showing or conclusion was wrong, or if I wrote in a manner tending to convey any other impression, I am sorry, and ask pardon. I certainly had no desire to do injustice to any.

Next, to offer prizes, and so put things by editorials or otherwise, as to draw out only one side, without putting the other side on an equal footing, is what I call misleading, and especially so where this is done in the reading columns of a paper in a way tending to point toward some financial interest of the promoter. If so calling was wrong, or if I wrote in a manner giving a different impression, I regret it more than any one else. Not till the "fad" for long tongues had nearly "spent itself," was there any call made for tongues to measure from colonies which had proved themselves inferior for honey-gathering. To have been fair this should have been done at the outset.

Then, when a person writes from an opposing side, and a foot-note is used so as to turn what the opponent says that it may point toward the fad—this is what I call twisting, and something our bee-papers of to-day should not stoop to doing it. If I am "off the track" here, I am sorry. I do not wish to look at things through a distorted vision.

Again, in closing my article I said, "There are times when it is necessary that a 'halt' should be called" by some one, and as no one had seen fit to do this, I felt it my duty to do so." Replying to this part, both Dr. Miller and E. R. Root point me to a certain editorial on pages 295-296 of April 1st (Gleanings), to show that a halt was there called, which I had made no mention of, and if I would be fair I would have noticed it. Well, if I had considered that editorial a calling of a halt I should have noticed it. Allow me to quote from it, similarly to the way Dr. Miller and Mr. Root did:

"The breeder who sells an untested mother of long-reach stock sells her for just what she is. Unfortunately, the buying of queens, even from the best of breeders, is something of a lottery; but if one will pay enough, and get tested stock, he then has some reasonable assurance of getting what he orders. The A. I. Root Co. will, if desired, sell tested queens whose bees will have a tongue-reach of a certain specified length—the longer the reach, the higher the price, of course; and I have no doubt that other breeders will do the same, providing that they learn how to measure the bees' tongues, or get some one who knows how to do it for them. We will undertake to measure the tongues of any bees of our subscribers for ten cents per cage of one dozen bees."

It seems strange that Dr. Miller, or even E. R. Root (who wrote that editorial), can see anything but a semi-advertisement in it, especially as immediately on the eve of this editorial, advertisements of the A. I. Root Co. appeared quoting queens at \$10, \$15 and \$25, according to guaranteed tongue-reach, and thus writing editorials which can be read either as the "calling of a halt" or as an advertisement, is what I called "rubbish," in my article. I do not like to see the reading columns of any paper thus prostituted, and so "spoke right out in meeting" about the matter. If, in any of these matters, I was too caustic, or did not use becoming language, I am sorry, for I do not wish unnecessarily to wound or offend.

Then Dr. Miller and W. Z. Hutchinson call my attention to the fact that they both "called a halt," the Doctor in "Stray Straws," and Mr. H. in the Review, which is right. But when they come to know that my article was written the first half of April, and that neither April 15th Gleanings nor the April Review reached this post-office till April 20, or later, it will be seen that I had seen neither of these at the time of writing my article.

Mr. Root seems to think that I am "way off" in thinking that any "fad" has been the means of wasting "thousands of dollars." Has he forgotten, or has he never read in back volumes of Gleanings, how a top-bar made of $\frac{3}{4}$ lumber and sawed only $\frac{1}{4}$ inch thick was pushed? and how folded-tin bars were, later on, placed between top and bottom bars, in the center, to keep it from sagging? And when thousands and millions of these frames were in use, because Gleanings pushed this thin, narrow top-bar, he wondered how bee-keepers ever tolerated such a nuisance (?) and told of the awful job it was to pry off upper stories and supers from them! Then Gleanings swung around to the other extreme and pushed a top-bar as much too thick (in my opinion) as the other was too thin. And all this time Doolittle was using a top-bar one and one-sixteenth wide by five-sixteenths thick for the Gallup frame, and the same width by seven-sixteenths thick for the Langstroth, and I so use them to-day, and so advocate, and have advocated for the past 30 years, notwithstanding Mr. Root's thinking that I have changed my views on the subject. And would not the using of millions of such "tolerated nuisances," and the changing over to a thicker nuisance (to say nothing of the vexation resulting from using such), cost up into the thousands of dollars?

Again, Mr. Root seems to think that I have been the chief promoter of "the rage for Golden Italians," but not he, nor any one else, can find where I ever advertised them, by circular or in any bee-paper; and unless I am greatly mistaken (I have not time to look the matter up now), he cannot find a single word in print, coming from my pen, where I have even mentioned them during the past five years. I once gave what I considered their origin, and once set right some mistakes regarding them, but no one can truthfully accuse me of "pushing" them. If I had desired to do so, the editorial columns of the Progressive Bee-keeper have been open to me during the last five years.

I may be wrong, but it seems to me that there is a vast difference between a contributor or an advertiser "having his say" in a paper, and the editor of the same paper, by foot-notes and editorials, pushing the same thing. With the former, there are other contributors and other advertisers to offset the first, but with the latter the editor stands supreme, and can, if he chooses, turn the current of thought in the direction he wishes, without any one effectually to gainsay in the matter.

In conclusion, I wish to say that I am not opposed to long-tongued bees, long-winged bees, or bees having large honey-sacs, etc., but I am opposed to the pushing of any of these in a sort of one-sided way, without at the same time trying to draw out the truth in the matter by giving the contrary side an equal chance. 'Tis time enough to push things after they are known to be right, and, to my mind, a thing should never be pushed by the editor or publisher of a paper until it is so known. Onondaga Co., N. Y.

Continued from page 471.

No. 10. — Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

NO drone-brood was found on any but the third and the fifth frames. When Mr. Bond inquired why there was none on the frame between these two, nor on the frames on the outside of the brood-nest, I reminded him of what I had previously told him about giving a new swarm a few frames without full sheets of foundation, for reasons also then stated.

"This frame to which you direct my special attention," I explained, "serves, better than any other in the hive could, as an illustration of the way my theory works, as applied to the drone question in bee-keeping."

"You see, here," I continued, as I took the frame in my hand, "how bees will sometimes take advantage of opportunities in their efforts to outwit the intermeddler, and to carry out their intuitive perception of the fitness of things in their household management. Had I given them a frame containing a full sheet of comb foundation, in place of this with a starter only two inches in width, they couldn't have made any drone-comb in it. They can not convert comb foundation into drone-comb—at any rate they have never been known to do it."

"Well, here is the explanation, Mr. Bond: When I hived that swarm I put only these two frames having starters in them into the hive—near the center. Four of the other ten had full sheets of foundation, and four were newly finished comb—not a drone-cell in any of them—taken from another hive, all nearly solid with ripe brood. So, you see, this colony had no chance to build drone-comb on any of the frames except these two; and here they tried to make up for it by using nearly the whole space of the frames, below the starters, for that purpose."

"But I don't understand," remarked Mr. Bond, quizzically, "why you allowed them to rear drones on these two frames when you could have prevented it, just as well as not. Didn't you say that you didn't want any drones here?"

"Perhaps I did say that," I replied, "and I confess that the whole matter has a queer look—must have to you. But the contradictions all disappear when I say: I forgot about those two frames, otherwise I would have exchanged them for drone-proof frames before the bees had time to build the drone-comb. It is true that I don't want these drones; neither do I want any more to hatch out in my apiary this summer. There are plenty on hand now to answer the only practical purpose that a sensible bee-keeper rears drones for."

"But, let me tell you, Mr. Bond, the regulating or controlling of the drone-business in an apiary of even 20 or 30 colonies, is, I believe, the most difficult task a bee-keeper can put upon his business program. It demands eternal vigilance to make the problem a success. It's a fight against nature, and therefore against many obstacles: some of them unknown until learned by experience, and nearly all of them hard to overcome."

"One of the most serious of the obstacles has just been pointed out by intimation when I said I forgot about these two frames. If every bee-keeper who tries to climb to the top of the business had a good, reliable memory, instead of a first-class forgettery, that alone would go half way, at least, toward success in the matter of regulating the production of drones by the bees."

"But I don't understand," remarked Mr. Bond, "why you should go to so much trouble to prevent drone-increase if, as you say, all the harm drones do is, that they eat honey and don't work."

"Mr. Bond," I replied, impressively, "it is honey I keep bees for. As far as drones are a help to me in getting the largest possible yield each year, I tolerate them, and don't interfere with the bees in their efforts to produce them. But when I know that my bees are rearing more drones than are needed for the only legitimate purpose, I am disposed to interfere, because I know that the honey eaten by useless drones is lost property. Besides, all the drones in a hive that are not really needed as a nuisance, because they are in the way of the workers during busy times."

"But," queried Mr. Bond, mischievously, "if bees have intuitive sense—as you have been trying to convince me—how can you make out that they don't know, intuitively, how many drones they really ought to have?"

"Mr. Bond," I replied, "bees have intuitive sense

enough to know that they can't get along without drones; but they don't seem to have enough of it to guide them to the fact that more than enough is too many. However, let us get down to business, Mr. Bond.

"I wish you to take a good look at this drone-comb and the brood in it, and compare it with the worker-brood just above it. You can easily see the difference in appearance, so that you will always know the one kind from the other. The principal distinction between them is, that the drone-comb projects out beyond the surface of the worker-comb. And that enables me, when I am destroying drone-brood, to slice off the heads of the matured but unhatched drones with my sharp, thin-bladed honey-knife, without injuring any of the worker-brood."

"That looks easy enough," remarked Mr. Bond, after seeing me perform the operation. "But, how do you get the beheaded drones out of the cells?"

"I don't try to get them out. The bees can do that, so I simply replace the frames as they are, and close the hive. Before sunset you will find most of those headless corpses out in front of the hive. How they manage to drag them out of the cells I don't know, never having watched them at the work."

"But here is another thing that I want you to look at, Mr. Bond," I said, holding the frame in my hand up before him and pointing to three queen-cells on one side of the comb. You told me yesterday that you had never seen a queen-cell. Hereafter you will always know one when you see it."

"So those queer-looking things are queen-cells," said Mr. Bond, meditatively. "Well, I declare! I never thought they were anywhere near so large—nearly the size of a small sewing-thimble, and full of little holes on the outside, too. Does the old queen build those cells?"

"The question took me by surprise, coming as it did from a man past middle age, and in dead earnest, too. But I repressed a strong inclination to smile, and told him the truth about the matter:

"No," I said, "the old queen has nothing whatever to do with it, except to lay the eggs from which the young queens develop. The worker-bees build the queen-cells, and when they are completed they fill them with bee-food, or royal jelly, as bee-keepers usually call it. The cells are then sealed up at the small end and the queen-larva lives on that jelly and grows until it is able to eat or gnaw itself free, and soon after crawls out to begin her career as a queen."

"Do you mean to tell me that a queen grows from the same kind of an egg that a drone or a worker comes from?" asked Mr. Bond, somewhat excitedly.

"Yes, and no, Mr. Bond," I replied. "A queen is reared from the same kind of an egg that produces a worker under ordinary treatment—that is, when reared in an ordinary brood-cell. Both are female eggs, but the workers are undeveloped female bees. But the drones are reared from male eggs. A fertilized queen can lay both kinds; and either kind at will."

"How do you mean that?" queried Mr. Bond.

"By that I mean that a laying queen can lay either female or male eggs, as she pleases. When she inserts the small end of her body into a worker-cell she usually deposits a worker-egg; and when she deposits an egg in a drone-cell it is seldom a female egg. That's the whole story, Mr. Bond; but it's a long way from being an explanation of the mystery, or, if you prefer, the philosophy, of the fact."

Mr. Bond looked very serious as he remarked, "I didn't think those things were possible. I begin to see that I know as little about bees as I do about bee-keeping. I see now, that to be really successful with a hundred colonies I must first learn how to manage one colony, up-to-date, as the saying goes."

"But tell me, please," queried Mr. Bond, "what are you going to do with those queen-cells?"

"I am going to put the frame they are on back in its place in the hive," I replied. "One of the young queens is beginning to gnaw the cap off her cell, you see"—showing him the cell, on the small end of which a slight movement was discernible—"and she will be making an inspection tour of the hive before to-morrow noon, I think. She will have to be watched or she'll destroy the other two young queens in their cells."

(To be continued.)

The Premiums offered this week are well worth working for. Look at them.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Advice to Beginners.

If you want to be in the front rank as a bee-keeper, you will do well to inform yourself upon all phases of bee-keeping. Some of you make the mistake of thinking, "Oh, that subject, or the other subject connected with bee-keeping, may be well enough for those particularly interested in that direction, but it doesn't come in my line, and I'll not waste reading it." And so you miss reading some of the very things you most need.

"How do I know you don't read everything?" I'll tell you how I know. Nearly every week—well, say once in two weeks—I get a question from some one when that question was answered not two months before. This summer the question that has come oftener than any other is the one referring to swarms absconding after being hived; and many has been the swarm lost because the loser didn't think he needed to know anything about absconding swarms until he had one of his own abscond.

Now, I don't want to choke you off from asking questions in the least; some of you don't do as much of it as you ought; but I want to suggest that you would be the gainers if you would read up in advance what is written for others.

Not so very long ago it was said to me, "I suppose you don't read a large portion of what you find in the American Bee Journal." That supposition could not have been wider of the mark. Except what was written by myself, I dare not omit the reading of any word. The short letter from some beginner may have no word of information to pay for the trouble of reading it, and then again one time out of a hundred it may; and I don't know which one out of the hundred may give some hint of value; so the only safe plan is to read the whole hundred. C. C. MILLER.

Swarms Absconding from the Hives.

Can you give any information about bees leaving the hive after hiving them? I have lost about half the swarms this year in that way. WISCONSIN.

ANSWER.—The absconding of swarms this year seems to be unusual. Doubtless it is on account of the unusual heat. Do all you can to keep your swarms cool by shading and plenty of ventilation. Raise the hive on blocks, and for a few days let the hive-cover be partly off.

Painting Barrels for Holding Honey.

Will it do any good to paint alcohol barrels that I intend to use for holding extracted honey? MINNESOTA.

ANSWER.—I don't know. I doubt if it will pay, and will be glad to be corrected if I am wrong.

She Has Troubles of Her Own.

I winter my bees in a shed, long and narrow with a door in the west end. I pack them in as warm as possible, and open the door on pleasant days. Last winter I put in 10 colonies, part Italians and part blacks. I gave the Italians the warmest places, and near the door where it was almost to the cold I placed a strong black colony. Last spring, on taking them out, the colonies near the door were just overflowing with bees, both blacks and Italians, while some of the other colonies seemed to have scarcely bees enough to keep them warm. One Italian colony, especially, had a queen and a mere handful of bees. As soon as the weather was favorable I divided the large colony, intending to give the queenless half to the small Italian

colony, but before I could do it the Italians were all dead. I immediately sent South and got two queens, thinking that, as I had the colony divided, and there were such a lot of bees, it would be a good time to Italianize them. I successfully introduced both queens, but those two colonies have just dwindled down to nothing. Yellow bees would hatch out and I would find them crawling around outside of the hives. One queen turned up missing. The other deserted her hive with a handful of bees. Now, where did I make a mistake? and will those combs do to give to other colonies? Do bees make a practice of going into different hives in winter?

ILLINOIS.

ANSWER.—To be entirely candid, I don't know enough to say just what mistake you made, or whether indeed you made any. Possibly a fuller knowledge of particulars might help in the diagnosis; possibly not. It is quite likely that the season had something to do with it, especially if you operated somewhat early, for the spring was unusually bad. It happens only too frequently that bees desert their hive and enter another, especially in a bad spring when there is more or less spring dwindling. It will be all right to give the combs to other colonies.

Swarming—Wintering Bees.

1. I started last spring with three colonies of bees, one of which has sent off two nice swarms, another cast one, and the bees issued from the third hive, and returned to the hive without clustering. In how many days thereafter may I expect them to issue again?

2. I have a room in the southeast corner of my house, with one window on the east side, and a door opening into a small, warm hall. Would it make a suitable place in which to winter my bees? If so, ought the window to be darkened entirely, and should a curtain or blanket be hung at the door, as it does not fit very tight? There is no way of warming the room, except by opening the door into the hall, but nothing ever freezes in it unless in the very coldest weather.

NEW YORK.

ANSWERS.—1. Hard to tell. It depends altogether on conditions. If the old queen was in the hive, they may come out the next day or so, or they may not issue again till a young queen is matured eight or ten days later. It is possible that the old queen was gone, and the swarm issued with a young queen, returning because the young queen could not fly, or for some other reason; in which case they may come out any time within two or more days, when another young queen is matured. It is also possible that a young queen was present and that the swarm was merely something like an escort for the young queen when she took her wedding-trip, and no further swarming will take place. So the full answer is that there may be no further issue, and that there may be one on any one of the following sixteen days.

Building Up Colonies for Winter—Buying Bees.

1. I have an apiary of six colonies. I purchased three large swarms two weeks ago, for \$3.00, and hived them in Hubbard hives, and I think they have stored 50 pounds of honey each. I have three others that are not doing so well; they are weak in numbers. How can I build them up for winter? I take the American Bee Journal and think it is a great help; I also have Prof. Cook's "Bee-Keepers' Guide." I am very new in the business, and need all the help I can get.

2. I can purchase colonies of black bees at \$1.00 each, or can purchase this year's swarms in good, standard hives at \$3.00 each. Which would be better to purchase, the early swarms at \$3.00, or wait till next season and get them at \$1.00? I want to go into the business heavy next season.

VIRGINIA.

ANSWERS.—So many things are to be taken into account, that it would almost take a book to tell all the different things it is possible might be done in order that your weak colonies have the very best chance to build up strong for winter. As the most valuable piece of advice in the case, I should say the very first thing is to study carefully your text-book. Then you will be competent to judge what is the best thing to do much better than one who has no opportunity to see the bees. It is quite possible that nothing need be done but to let the bees alone; and that they will of themselves build up strong for winter. See

that each has a good laying queen. If you find four to six of the brood-combs mostly filled with worker-comb, it is likely no interference is needed. If you find everything not all right in this respect, it may be that something is wrong with the queen, and that she should be replaced.

2. If I understand you rightly, you can get colonies in hives now for \$3.00, and next year you can get the swarms when they issue, without any hives, for \$1.00 each. It is hard to tell which would be best. Possibly a compromise might be a good thing, getting half the number now, and filling out the quota with next year's swarms.

Pays to Get Fresh Blood—Bee Veils and Gloves.

1. I have a few swarms of bees, the most of which I gave Italian queens, which I purchased from an Iowa breeder last year, because it was not far to mail them, and I am well pleased with them, they having built up very strong colonies of good workers. I intend to buy some more queens this year, and the question is, Shall I buy from the same place, or from somewhere else, so as to get new blood in my apiary? What would be your advice?

2. I have a veil I made myself that I like the best of any I have seen. I first take a straw hat with medium rim, then I get a piece of common window-screen about eight inches wide and long enough to go around the rim of the hat, and sew the ends together; then sew a piece of cloth over the top a little loose, so the crown of the hat will set up in the cloth; then sew a piece of mosquito net or cheese-cloth on the bottom about 14 inches wide; slip the hat inside, and put it on and button the coat or vest over the bottom, and it is bee-proof, and will not blow against the face nor tear easily. I find I can see better through it than almost anything else. For gloves I take a pair of soft, cheap leather gloves, and sew on some long wrists made of thick cloth that will come nearly to the elbows. With this and my bicycle guards on my pants' legs, I can handle bees with as little fear as if they were chickens.

MINNESOTA.

ANSWERS.—1. Other things being equal, there will be some advantage in getting in fresh blood.

2. If you make much use of a veil you may injure your eyesight by looking through wire-cloth. If I remember correctly, one of the veterans had a very bad time with his eyes years ago in that very way. It is better to have a veil that does not require either coat or vest, for bee-keeping is too hot work a good part of the time to wear either.

Biographical.

MR. FRIEDEMANN GREINER.

(On the first page of this number appears the portrait of Friedemann Greiner, one of the American Bee Journal's best contributors.)

His love for insects and insect life manifested itself early in his younger days. As a boy of six or seven he well remembers spending hours and hours at the old beehed of his grandpa's, watching the bees go in and out of the straw-skips; and what pleasure it afforded him! The school-lessons, and he regrets to say hours, were clean forgotten many a time. Too often did he have to hear the chiding words from the teacher when his home study had been neglected: "Well, Greiner had to take his grandfather's bees out to pasture; couldn't attend to his study."

Mr. Greiner was not all concentrated in bees, but other insects shared likewise. His collections of butterflies, bugs and beetles aroused the envy of his schoolmates. Many days did he spend in the search of rare caterpillars, which, when captured, were fed daily with such food—leaves, plants, etc.—as comprised their accustomed food. When finally the caterpillar had gotten its growth, spun its cocoon, it was with much anxiety that the forthcoming of the butterfly or moth was awaited. When this happy moment did come, the specimen was treated to ether, thus killed, and then prepared for the collection. He always knew where to find rare specimens of water-beetles, etc.

When his grandfather died, the bees went into other hands, and for years not much thought was given them.

But soon after he arrived on the shores of America, at the age of 20 years, his interest in the little busy worker was rekindled, and developed into a disease known otherwise as "bee-fever."

With great enthusiasm he took up the bee-business as his life occupation. Not being sufficiently conversant with the English language, the German bee-literature was studied first. Standard works and bee-keeping periodicals were read through. Bee-keeping was gone into with great anticipations and enthusiasm. Finally, the study of the American bee-literature was taken up, and, by reading the leading bee-papers regularly, he tried to keep up with the profession.

Two hundred colonies are the most he has owned at one time, keeping them in several apiaries. Two years were also spent in Virginia in search of a more favorable location for bees. He finally decided to stay in New York, where he owns a small farm devoted principally to fruit-growing.

Mr. Greiner's anticipations to become rich through bee-keeping, did not materialize, but, loving them, he sticks to them, always having some experiment going, sometimes being on a wild-goose chase, sometimes after realities, but the pleasures he secures, he says, are many times greater than the profits.

※ The Afterthought. ※

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

BEE-KEEPERS' EXCHANGES.

Sometimes an argument is a sword which cuts both ways when the one who uses it thinks it cuts only one way. Mr. C. A. Hatch, in arguing for exchanges, says it is only when the soldier ceases to be an individual that the army becomes a power. That sounds conclusive—perhaps is conclusive—but those of us who value our individuality too much to give it up might quibble a little thus: The British soldier is more an individual than the Russian soldier; the American soldier is more an individual than the British soldier; and the Boer soldier is more an individual than the American. We do not consider the above succession a diminishing, but the opposite. And is it not true that the individuality of the Boer is the very thing that makes him terrible? Now if the Russian and German armies overdo the business of taking away individual initiative, may it not happen that our bee-keepers' exchange will do the same thing?

REPUTATION AS A HUMORIST.

I shall get a reputation as a humorist if the proof-reader keeps on helping me. On page 473, in the place of "800 years" during which the family was to abstain from honey read—something else—probably simply for years. Also instead of punctured with dead flies read *punctuated* with dead flies.

SWEET CLOVER.

The Wisconsin Farmers' reply about sweet clover, on page 397, seems to me to be, in the main, a calm and reasonable article. Being brief it did not detail the good points as we might have done. I fear that rejoinders like Mr. Abbott's are too well calculated to make the great, big outside world of mankind think that we are a small group of cranks—cranks incapable of recognizing beans, when the ligature of the bag has been only loosened before our eyes. Many years ago I introduced sweet clover into my garden. For most of the time it did practically no harm—that is to say, made me little if any more work than the other plants would, which, in the absence of the sweet clover, would have been claiming the same space. Quite recently it has made itself a sad nuisance in the ground occupied by asparagus and winter onions and strawberries. Too tough to hoe out, or chisel out, too strong to pull, and with multiplying powers like the potato bug's. This power gradually to fit itself into new situations is a dangerous one. In my early enthusiasm for sweet clover I sowed some by the roadside (not beyond my father's estate, however) and to the best of my knowledge not one plant from that sowing ever came to bloom. But after say a dozen years it began of itself to travel out from the garden along the road, and is now abundant for quite a distance.

DR. MILLER AND HIS 70 YEARS.

And so our beloved Dr. Miller, senior member of the staff, is seventy years old. The burden of declining years is but poorly got rid of by pretty speeches, but we will hope that the "labor and sorrow" of which Moses speaks so pathetically may be specially lightened in his case by that Power which overshadows and holds all our lives. It turned out so in Moses' own case. Moses probably wrote that psalm when he was a little past seventy, expecting the next ten years to be weary ones, with death somewhere near. It turned out that he didn't begin to live on a grand scale until he was eighty, and that he finally died at a hundred and twenty without his eyes being dim. Courage and cheer, O comrade! When on earth heaven shall be open, and the servants of God ascend and descend upon the Son of Man, you and I shall come from one of the planets of Alpha Centauri, where we have been telling good news (and introducing bees?), and our eyes shall not be dim, and our hands shall not tremble. Pages 401 and 402.

BREEDING BEES.

It looks possible, dear "boss," that a cross between poor-looking hybrids and five-banded *might* result in three-banded bees—to the confusion of the purity rule. Let's not be too sure of it, however, till some reliable observer has seen it. From what we know of crossing, and its relations to sporting, we would be much more likely to get a colony of all stripes and colors from five hands to none—no evenness in anything. Page 403.

HOW TO "SPOT" DRONE-COMBS.

Red spot painted on the bar right over a patch of drone-comb. Thanks, Mr. Doolittle. Those who wish to do the utmost in the line of controlling drones will do well to take heed. Page 403.

※ The Home Circle. ※

Conducted by Prof. A. J. Cook, Claremont, Calif.

RECREATION.

If the various home circles could now (July 17), look in upon me and mine at this delightful vacation time, no one would wonder at my theme which I bring into the homes to-day. Where are we? Away up among the Sierra Madre mountains. While we read daily of the terrible heat in all the Eastern cities, I am writing this early morning with my heavy winter overcoat about me, and half wishing it were warmer. While our friends of Kansas are mourning because the rain comes not, our tent is pitched close by a rapid mountain stream, whose waters, fed by the snows hard by, are as cold as they are pure and refreshing. As we lie in our beds, the rippling waters, as they dance over the rocks, sing to us all the night long. This swift-running mountain stream divides just above where we have fixed our vacation sojourn, so that they hem us in, and we are really on an island. The little valley in which our rest-days are flying so rapidly by, that we sigh that the end will come so soon, are so heavily wooded that both shade and seclusion are ever awaiting those who wish to enjoy them. The great mountains, which shut us in on all sides, are also heavily wooded, and we rejoice constantly in the soft, green landscape which holds us in its embrace.

Northwest of us is "Old Baldy," which reaches nearly 11,000 feet skyward. Its snowy summit is only sixteen miles away, and tomorrow our party of eighteen are to scale its heights. It is a cool, delightful, restful place.

I think I have before counted our Southern California blessings in these home papers. The marvelous scenery everywhere; high mountains, grand as beautiful; lovely valleys verdant with alfalfa fields, and resplendent with beautifully kept orchards; incomparable climate, which knows no winter, no sunstroke, but which hands forth warmth and sunshine every week the year through; delicious water that comes pure and sparkling right from the mountain rocks. If typhoid germs, or other taint from water, ever come to blight our Southern California homes, it will speak of gross neglect or carelessness in the homes that are shadowed; most luscious fruits, our party right from our own orchards and gardens bring for our refreshing—oranges, lemons, pomelos, plums, apricots, apples, peaches, and I might have added strawberries, blackberries, raspberries and nectarines. And all these

so sweet and delicious that they nearly melt in the mouth; and, as I usually say, best of all, a grand, true, splendid citizenship. Doubtless God might have made a better people than sojourners in our beloved sun-kissed California, but doubtless God never did.

This usually completes my summary, but I desire to add another. Almost all our Southern California homes are so close by sea and mountain that either are within a day's journey by horse, or a few hours by cars. Thus if heat does come, we can feel its presence, and bathe in the clear, pure, delightful mountain air, or the warm, refreshing water of the ever restless Pacific. This is no mean advantage. How many hundreds of homes and hearts have been recently saddened in the East, as drought hurried on by the crushing heat, has snatched the loved ones, forever away. Here such crises never come to menace, for at the seashore, or in the mountains, we are safe—always safe—from their evil work. I hardly know which I enjoy most—the wondrous air of the mountains, or the luring breeze and bracing waters of the ocean. When here, I think the mountains hold forth superior charm; when there, the sea seems to offer most that enamors, and invigorates. Either is delightful, and we rejoice with fervent thanksgiving that we can taste so easily and often of both.

Do we in all our home circles think enough of recreation? We are a very earnest people. So intense are we in our business that I fear we often lose sight of the good that may come from the picnic, the camping out, the mountain sojourn, or the weeks by the seashore. We are so fashioned, that the wheels of our human machinery run more smoothly, and with a surety run longer, if we tend them ever and anon in different grooves. Just as the stomach wakes to greater strength and added energy when given a variety to work upon, so the whole body craves new scenery, new activities, a halt in the everyday round; and a push into work or play that recreates, because new and fresh.

Let us all, in every home circle, plan as best we may to find time to break from the usual routine of work and duty, and in some forest, or by some lakeside, alone, or better, with other families, seek out a different life, and thus make the young younger, and carry youth into old age. And more than this, we will find that we will come back to the usual duties with so much of added strength and vigor that oftentimes we shall soon more than make up for the days of absence, as we will easily do more and better work.

In planning our outing, let us not only arrange for pleasant friends, and wholesome fellowship, but plan for games, music, and reading. Last night we met with many other campers, and had a splendid concert. A piano had in some way reached this retreat, and we did sing with genuine spirit.

I heard more than one say as we said our adieus, "It has been the pleasantest time since we came." For the children, Captain January, dear daughter Dorothy, and John Halifax Gentleman, will be a valuable part of the company. Fishlines, croquet balls, and hammocks galore, should not be forgotten. Let us all remember about Jack and the all work and no play, and endeavor to make the too just criticism of our English friends—that we think too little of rest, recreation and a good time—less true.

THOUGHTFULNESS.

There are few things that will reveal character like a few weeks' camping. We soon find that some of our party are so thoughtful, so helpful, that we could not have spared them. They are always just where needed; they are ever planning, and successfully, to make all more happy. They are so handy in fashioning the conveniences about the camp, so fertile in preparing meals, so handy in keeping all neat and tidy, that they really are like "a thing of beauty." Were I a young man or woman, and in pursuit of information regarding the character and temperament of some special person of the opposite sex, I should arrange to be for a month in a camping party with them.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us *one new* yearly subscription to the American Bee Journal at \$1.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

DESKS FOR GENTLEMEN AND LADIES!

Combined Desk and Book-Case
Size, 66-in. high, 36 in. wide,
19 in. deep.
Price, \$13.75.

THESE DESKS are made of quarter-sawed oak, first-class finish, well put together, and will please every purchaser. They are an ornament to any home, as well as being a useful necessity. Would make a FINE GIFT for father, mother or sister.

The Combination Desk and Book-Case

is just the thing for a farmer or business man of any kind, to keep his private papers in, and for his books, etc. The drawers have locks, and there are a number of pigeon-holes inside each of the desks shown herewith.

The low prices quoted are f.o.b. Chicago. Send for free catalog. Address,

The Royal Star Combination
Game-Board Co.,
773 to 779 Carroll Ave., CHICAGO, ILL.

[The above firm is entirely reliable.—EDITOR.]

Please mention the Bee Journal

Ladies' Desk.
Size, 40 in. high, 25 in. wide, 15½
in. deep.
Price, \$2.85.

To Our Shippers :

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "HILDRETH, McCaul Co.," and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name HILDRETH in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract :

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120-122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs; it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are hereby restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the the defendant at No. 120-122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of "Hildreth" separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDRETH & SEGELKEN,

265-267 Greenwich Street, NEW YORK, N. Y.

GENERAL ITEMS

A Fine Honey-Flow.

My bees were just able to make a living up to June 28; since then we have had a fine honey-flow from basswood and sumac. I will have 1000 sections from this flow, and at this date about one-half has been sold right at home.

L. B. McDANIEL.

Athens Co., Ohio, July 22.

Bees Carrying Eggs Down.

Is this anything new? Two weeks ago I noticed a colony of my bees, which had swarmed in the spring, had failed to provide themselves a queen, so as they had a super on. I experimented by cutting a comb about a square inch containing eggs from another colony, and grafting it in one of the sections in the queenless colony's hive. Three days later I looked at the job, and the eggs were gone. To-day I looked among the brood-frames, and found a little patch of sealed brood about an inch square, and a queen-cell nearly ready to hatch. Clear case of carrying brood (or eggs) down, isn't it?

Walker Co., Ala., July 13. R. V. Goss.

Best Honey-Year—Swarming.

This is the best honey-year we have had in northern New York for three years. There is lots of white clover and basswood. It has been almost impossible to stop swarming; when I returned them, the second night, they would come out again, so I lift up the back part of the hive and run them in that way, and they almost always stay. I have not had a swarm come out when put back in that manner.

J. S. DEAN.

St. Lawrence Co., N. Y., July 11.

Very Dry in Indian Territory.

The bees here in Cherokee Nation are doing nothing on account of weather. Out of 48 colonies, spring count, I got 4 swarms. The bees loaf and cover the hives. I have raised the hives an inch from the bottom-board. If cotton-bloom has any honey there ought to be great quantities of surplus, as no swarming has made them very strong. So far this season we have had nothing for them to gather. If the cotton proves failure, not half the bees will have enough to winter on. The hot winds are burning everything up. The fruit burns or bakes on the trees; corn and grass look as if a heavy frost had struck them. The leaves on the trees are falling like in October. The oldest people living never knew the rivers and streams so low, and many are dry. The Indians are "conjuring" and burning great bonfires and all the big drifts on the rivers, for rain. All over the Indian territory there is almost a total failure of crops, and unless it rains in a very short time corn and grass will burn up.

R. N. CRAFTON.

Cherokee Nation, Ind. Terr., July 13.

A Report from Arizona.

On page 435 we read what Editor Root says about the heat of Arizona, which probably is correct, but I desire to call attention to the fact that there is just 30 degrees difference in the effect of the heat between a damp and a dry atmosphere. At Chicago, my former home, or in most of the Northern States, if you wrap a thermometer with a damp cloth it will register about the same, but here it will drop 30 degrees. I am now taking butter by keeping the milk in a eupboard outdoors, with a tank on top filled with water, which drips down on burlap on all sides; the air passing through the damp cloth lowers the temperature.

I have been running the extractor con-

tinually while the thermometer has been registering from 104 to 114 degrees for the past three weeks. The frames must be wired to extract when over 110 degrees.

The mesquite was only half a crop this year, and as last year was very dry the beekeepers lost heavily in bees, by the queens dying from old age, and the drones having been killed early. The young queens failing to mate caused heavy losses, hence the honey crop this year must be short.

The beekeepers held a meeting and decided not to ship any honey until it will bring what it ought to be worth. The banks advance money to all who must have cash to meet present needs. Eastern beekeepers need not fear our demoralizing the price of honey. In the first place, we haven't more than half a crop; secondly, we propose to hold what we have until it brings a fair price.

Water for irrigation is now scarcer than was ever known, and the country is overstocked with cattle, hence no more wheat blight for this year, unless heavy rains come soon.

B. A. HANSELL.

Maricopa Co., Ariz., July 18.

Poor Honey Season.

It is an awfully poor honey season here; I will get but little comb honey. It was too wet and cool until about the last of June and first of July, then it was too hot. We are now having a wet time, and our wheat is cut and unshooked. I have a large crop of wheat, but little hauled in. My hay and corn promise a large crop.

L. A. HAMMOND.

Washington Co., Md., July 15.

Good Season for Honey.

So far it has been a good season for honey, plenty of rain and the most hot weather I remember ever seeing in one season—temperature from 100 to 106 in the shade a number of days during the past two weeks, yet the bees are storing honey very fast. I have about 300 pounds ready to take off, and shall commence to take off to-day.

I started in the spring with nine colonies. I now have 26 strong and good, and several colonies have cast two swarms each, and besides, have filled from 24 to 36 one-pound sections. Several of the after-swarms have filled the hive and are working in the boxes. One old colony has cast three swarms, stored 36 pounds of section honey, and are now filling the second supers.

S. B. SMITH.

Millelacs Co., Minn., July 22.

Management for Little or No Increase.

Of course, there will always be more or less weak colonies in the spring, but never rob the good ones of brood to build up the poor ones. Have your apple-blossom swarms in the hives in which colonies have died during winter. The brood reared in these combs will be clover workers in late June and July.

Real swarming will usually begin before the full honey-flow, frequently two weeks, or even more. These swarms should be left in the weak colonies, after removing and razing the queens in the weak colonies, and given plenty of room in the surplus chamber. The next day, between noon and 3 p.m., when most of the old bees are in the field, remove all queen-cells from the colony from which the swarm issued, smoke thoroughly, and turn the caged queen loose on the combs. The former weak colony is now one of the best in the yard, and the colony from which the swarm issued, having been supplied immediately with a laying queen, in two weeks' time, or less, is about as good as ever. Colonies so treated will rarely swarm again during the season; but don't forget to give plenty of surplus room.

Continue this until all the colonies in the apiary are ready for a rush of honey at an hour's notice, or less. Then, if a slight increase in the number of colonies is desired, remove one-half the brood from the colony that swarms, fill up the comb foundation and reduce on the old stand, raise the front of the hive one-half inch for ventilation, and place the removed combs in a hive on a new

To make cows pay, use Sharple's Cream Separators. Ask "Business Dairying" & Cat. 212 Free, W. Chester, Pa.

stand. The next colony that swarms treat in the same manner, and place the brood removed in a hive close beside that taken from the former hive. Give these nuclei ripe cells from your best colonies, and when both queens have laid their brood-chambers full, remove one queen and unite. This is now a first-class colony at once. The surplus queen should now take the place of the poorest one in the yard.

Should no increase be desired, hive as before, and set the brood one side. Have the next swarm that issues also with this swarm by shaking the bees down a yard from the entrance, and catching the queen as she attempts to run in. Return her to the hive from which she came, and give her the extra brood from the other colony. Now place plenty of sections on the double colony, give plenty of ventilation, and you will be surprised at the honey stored in a brief time. Should the season warrant, in about one week contract No. 2 to six combs and put on sections.

Usually a heavy run of honey (here at least) coming on suddenly puts a stop to swarming. I have known more than one-half of my colonies to start cells on a light run of buckwheat honey, but the main crop coming with a rush has prevented a single swarm issuing.

If in a locality where there is a run of buckwheat, or other honey, run the middle of August through September, do not let brood-rearing slacken after clover, but keep all queens busy, as only eggs laid before July 20 can be of much account for such a honey-flow; also, know approximately the date of commencement of the different honey-periods, and remember that it is work done by the queens five or more weeks previous, and not during the honey-flow, that gives the surplus, and that at the commencement of a honey-flow every cell in the brood-nest should contain a young bee, so that the surplus *has* to be stored in the stores.

Be ready for the season, and when your time is worth from five to ten or more dollars per day in the apiary, don't be caught anywhere else.

Wm. W. CASE.
Hunterdon Co., N. J., July 15.

Beginning Bee-Keeping Again.

The spring and winter of 1900 I lost all of my bees from some cause, and became discouraged and stopped all of my bee-papers except the "Old Reliable," have again made a start in bees, buying two colonies in box-hives, and increased to six in movable-frame hives. I have 25 hives and fixtures that I made two years ago when the wreck came. We have an old-time honey season now, the first in four years. If it doesn't get too dry it will be a glorious honey-year. I took off some fine honey yesterday—the first in two years, and you may be sure, Mr. York, it tasted good. You can imagine a lover of nice clover honey, and don't think he was not thankful.

F. McBRIDE.
Hardin Co., Ohio, July 21.

Harvest Rich, But Short.

The honey harvest has been rich, but rather short. At the beginning of the white clover bloom the weather was cool and wet, and the flowers did not yield much nectar, but after a while it turned warm, and the bees made up for lost time. With the yield of honey the bees commenced to swarm. I have not had so much swarming for a long time. I have several large colonies, where two prime swarms went together. I put two of them on scales, and kept a record for several days. One was hived June 18 on empty combs in a 10-frame Langstroth hive, with two upper stories filled with nine combs each. On the morning of June 19 they weighed 93 pounds; June 20, 96 pounds; the day being windy and showery; June 21, clear and warm, 146 pounds; June 22, 159 pounds; June 23, 131 pounds.

The other was hived on empty frames with two surplus cases of 32 one-pound sections each, filled with comb foundation; weight on the morning of June 22, 111 pounds; June 23, 114 pounds; and June 24, 122 pounds.

I had 29 colonies to start with, but there was enough honey in the fields for 200 col-

nies to have done equally well. Last year I had 15 colonies, and it was all they could do to get one-half as much honey.

Since the close of the white clover harvest the bees have been working some on red clover, not alone the long-tongued, but also the short-tongued, the 5-banded and 3-banded, hybrids, and other bees. In fact, bees will work to some extent on red clover in this part of the country for a few days every year, if they have the right kind of weather.

Say, Mr. Editor, if we stretch the bees' tongues is there no danger that we may shorten their stings?

The weather is extremely hot and dry at present, the thermometer ranging here from 100 to 108 degrees in the shade. My bees are exposed to all the rays of the sun; there are no shade-trees over them. In ordinary warm weather they usually hang out, but this is too much for them, and during the heat of the day they all go into the hive and come out again as the day draws to a close. How they keep the combs from melting down is more than I can understand. My hives are painted white, are set on posts about 4 inches high, and the grass and weeds are kept down with a lawn-mower. The covers of my hives are the old style 7½-inch, telescoped caps, resting on cleats like the Dadant hive.

I have extracted 1400 pounds, with about 200 pounds more on the hives; and I took off 200 one-pound sections, with 120 more to take off as soon as the weather gets a little cooler.

FRED BECHLY.

Poweshiek Co., Iowa, July 22.

Question on "Jouncing" Bees.

I am quite taken with Mr. C. Davenport's "jouncing" out the bees (page 420). I find that a frame 9½x17½, solid full of honey, lifted from a fourth 10-inch story, is more than I can manage to shake the bees out of into the hive. Perhaps an old and experienced bee-keeper could. Then, a hive with 10 such frames has quite a tendency to "jounce" down on the ground, and if lifted from its resting place, and to tempt to carry it to the honey-house—I would rather wheel 60 such frames in a cart. But there, to me, appear difficulties. I sometimes find a frame with just a little rim of honey over the top, and the balance of the frame full of unsealed brood and eggs, or perchance a nice queen-cell. I do not want to injure the bees, or want to put them through the extractor or "jounce," while some of the frames in the same story are full of honey that ought to come out. Then, again, not using an excluder the queen may be in any story, and of course, "jounced" out with the rest, or possibly carried to the honey-house, and left the hable bee lost, and not get back into the hive. In brushing them off she is of course brushed off with the rest into the hive, but when there are 2, 3 or 4 stories (and I would use still more if I could handle them so high), as each story is emptied it is set off on the ground to get at the one below—a frame I do not want to extract from is left in the hive. I have occasionally found the queen turn up missing. How would Mr. D. do in such cases?

This is my first experience with bees, and I am after all the information I can get on bees and their management. All I have learned of bees so far I have gotten from text-books and bee-papers. As to papers, something new is coming up in every paper, and I want to know all about them. I met a man a few days ago who said he had been keeping bees six years—said he had been taking a certain bee-paper, but had quit; intimating that the papers could not teach him anything. Where do you class such a man?

A Queen-Rearing Agent.

If that is the proper term to apply to the man contemplated in J. H. Martin's scheme, he is strongly endorsed by Mrs. A. J. Barber in the Rocky Mountain Bee Journal. Referring to the difference in bees, she says that last year one of her colonies produced 216 sections, two others 168 each, while the rest produced from nothing to 96 sections each, and continues:

Now it seems to me that if we had a kind of queen-rearing station somewhere, in charge of a competent person, that it would pay us to look out for such queens and send them to the place to breed queens from, thus securing stock that had been tested as to its working quality. I would gladly furnish two or three of my best queens every year for the sake of being able to get queens that were reared from a really well-tested stock. I mark my hives of the colonies that make an extra record every year, always expecting to rear a lot of queens "next year." Next year always finds me just a little busier getting a honey crop than I was the year before, so I am lucky if I get a dozen queens from any selected stock, after all. I would rather pay a good price for queens from stock that had had a practical test, as honey-gatherers, than to have the kind of queens we usually get, given to me. If all my queens last year had been as good as the three best, I should have been several hundred dollars ahead. Can't we do something along this line? Have the honey-producers furnish stock that has had a practical test, and get somebody to take it far enough from common bees to keep them separate, and rear queens for us.

Staying Foundation with Wood-Splints.

B. F. Averill speaks very highly of these in Gleanings in Bee-Culture. His plan seems to be an improvement on that of Dr. Miller. He says there is no need to have the splints waxed, although Dr. Miller says when they were not waxed the bees tore them out. Mr. Averill says further:

These splints were 3-32 by 1-16, and $\frac{1}{4}$ inch longer than the inside depth of the frames. A saw-kerf is required in both top and bottom bars for the insertion of the ends of the splints. These should be $\frac{1}{4}$ deep. No fastening is required if the sheets of foundation touch the top-bars the entire length. Otherwise the foundation bulges from the weight of a new swarm, and irregular, wavy combs are the result. Seven splints will answer to the frame with medium-brood foundation; for light-brood, eight splints would probably be required. With foundation wired from the inside, the foundation would still have to be attached to the frames; with the splints, the foundation is put in the frames, and securely stayed at the one operation. I could put in frames from 100 to 125 sheets per hour, with the splints, and I never have seen more perfect combs, all things considered. They stand extruding remarkably well. No cracks appear in the combs from this strain, as with horizontal wiring. I wrote you a few years ago about this matter, and again am prepared to say that you can advocate the general adoption of wood-splints for foundation brood-combs, without hesitation as to their giving any dissatisfaction.

In putting in the splints, a board of suitable thickness is placed inside the frame. Put four splints in place, then lay on two sheets of foundation; then put the other splints in place, and roll them down with moderate pressure. Turn the frame and roll down the first splints; and this completes the job.

Bee-Keeper's Guide

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try it. Will YOU have one?

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal
one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter,
Cabinet Maker, Machinist, Wheelwright and
Quarryman, Farmer, or any one using a grind-
stone, should have one of these Tool-Holders.
One boy can do the work of two persons, and
grind much faster, easier and with perfect
accuracy. Will hold any kind of tool, from
the smallest chisel to a draw shave or ax.
Extra attachment for sharpening scythes,
blades included in the above price. The work
is done without wetting the hands or soiling
the clothes, as the water flows from the opera-
tor. It can be attached to any size stone for
hand or steam power, is always ready for use,
nothing to get out of order, and is absolutely
worth 100 times its cost.

No farm is well equipped, un-
less it has a Tool-Holder. Pays
for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fast-
ened securely in the Holder by a
set-screw and can be ground
to any desired level by insert-
ing the arm of the Holder into
a higher or lower notch of the
standard. While turning the
crank with the right hand, the
left rests on an steady the
Holder; the Tool is moved to
the right or left across the
stone, or examined while grind-
ing, as readily and in the same
way as if held in the hands.

For grinding Round-Edge
Tools, the holes in the stand-
ard are used instead of the
notches.

GEORGE W. YORK & CO., 144 & 146 Erie St. Chicago, Ill.

Why not get out a few of these splints, and give them a trial? I am convinced that they will meet with your approval.

Artificial Swarms.

The editor of the Rocky Mountain Bee Journal says:

The method we use and prefer is to place a new hive filled with foundation starters on the old stand; shake off about seven-eighths of the bees, including the queen; put on a super of sections filled with full sheets of foundation. If honey is coming in the bees will at once enter the super and work there clear through to the end of the flow. A queen-excluder should be placed between the super and the brood-chamber. The old hive containing the brood and remaining bees should be moved to a new stand and given a ripe cell or a laying queen. By this plan we get a rousing colony composed of all the field-bees and a large force of nurse-bees and comb-builders. If the division is made at the beginning of the flow, the old colony will hatch out bees enough in 15 days to be apparently as strong as ever. With us this plan of increase is preferable to natural swarming, as it can be attended to at just the right time to secure the best results.

Swarming, and Section Honey.

"Hello, Doolittle! Awful hot to-day. My hives are covered with bees hanging out, and I fear they are going to have a swarming-time just when basswood is at its best, as it will be in ten days now. What method do you use in order to keep the bees from swarming just when it is important to keep the hives crowded with bees in order to secure a good yield of section honey?"

"You are not the first one to ask such a question. Mr. Brown, for this is something bee-keepers have been asking during the past quarter of a century. If the apiarist has done what he could to get his hives full of brood at the proper time, he will have lots of bees in time for the honey harvest—hives overflowing with bees, as you say yours are now; and in order to be successful with them, all swarming should be done before the height of the season arrives."

"But I supposed you did not allow your bees to swarm, for, I am told, no large amount of section honey can be obtained if we let our bees swarm."

"In this you err, for the swarm and parent colony, if rightly managed, will do fully as much with the average bee-keeper, when just one swarm is allowed to issue, as could be gotten were they not allowed to swarm; and, besides, if we tried to keep them together by cutting out queen-cells, giving extra section-room, etc., we would, as a rule, only delay swarming, so it would come during the last half of the honey harvest, when it would be the most detrimental to our interests."

"But is there no such thing as non-swarming hives, used when working for section-honey?"

"Whenever I hear men talking about non-swarming hives in connection with producing section-honey, I feel quite a little like doubting their practical experience as apiarists."

"Well, what is your method, if you do not use non-swarming hives, and let your bees swarm at will?"

"All my early swarms are hived singly in a hive having but five frames in them, using a starter of comb foundation about half an inch deep, and the sections are put on at time of hiving, as five frames give hardly room enough for a large prime-swarm."

"What do you mean by those coming early?"

"Such as come out from 10 to 15 days before the main honey harvest, which, in this locality [Oneida Co., N. Y.] is generally from basswood."

"And do all of your colonies obey and swarm during those five or six days?"

"No; I do not have all swarms come out just as I might wish, but I have a different plan of management for those that come later, say from five to eight days before the harvest. These later ones are united, so that two are put in a hive filled with combs, the

section-boxes being put from one of the old colonies on the hive containing the united swarms. Then this old colony is put on a new stand, and the hive containing the two swarms is in its place, thus giving all the field-bees from this colony, in addition to the two swarms, which makes a colony which will do wonderful work during the honey harvest, a colony from which I take 100, 150, and even 200 one-pound sections of the choicest of honey, according as the season progresses.

"But what about the queens? Do you let both go in with the double swarms?"

"No. The queens, having their wings clipped, give me the power of disposing of them as I think best, and so I let the queen go back with the colony which was moved to a new stand, and allow the one from the colony not moved to go with the united swarms. The moved colony being not only the swarm, but also all of its field-bees, feels so poor that the queen-cells are torn down, and all idea of swarming is given up; but this colony soon picks up from the multitudinous emerging brood, so that often it will do quite good work in the sections."

"But will there not be after-swarms from the colony going to the new stand?"

"The hive furnishing the queen for the doubled swarms is not disturbed in eight days, at which time the first young queen will have emerged from her cell, when the hive should be opened and all queen-cells destroyed, which will entirely prevent any attempt at second or after swarming."

"But if all have not warmed up to within a day or two of the opening of the harvest, what do you do with them—keep on uniting two swarms?"

"No. All that have not swarmed at the commencement of the honey harvest are made to swarm in this manner: A hive is filled with frames of empty combs, or those partially or wholly full of honey, and placed upon the stand of one of the colonies which has not swarmed, and all the sections are taken off and placed thereon; then all the bees are shaken and brushed off their combs of brood and honey in front of this prepared hive. Thus we have the queen bees, partly filled sections, etc., which make a colony ready for business at once. Previous to this a few nuclei should have been started, so that we may have the needed laying queens to use. Now take all the combs from which the bees were brushed except one, arrange them in the hive, carrying it to the stand of another colony which has not swarmed. Next take the comb of brood which was left out, and go to another nucleus, take the frame of empty, laying queen on it, and put the comb of brood in its place. Take the frame (bees, queen, and all) and set it in the place left vacant for it when arranging the combs of brood. Put on the sections, and when all is complete move the colony, not having swarmed, to a new stand, and set the prepared hive in its place. Thus we have at laying queen and enough of her own bees to protect her, combs full of brood, and all of the field or old bees from the removed colony, which make a colony that is ready to go into the sections in a very few days. The removed colony has simply lost the old or field bees, so as to stop the swarming impulses, and in a week will be ready for work in the sections again."

"That sounds good, and I believe I will try some of my colonies that way. But don't you think non-swarming would be desirable under any circumstances?"

"Yes, I certainly do, especially for out-apiaries. We have many of our best beekeepers at work in the matter, and I fully expect that, before the year 1925 shall be ushered in, something of universal value will have been brought out for the benefit of the fraternity. But the above is as good as anything in sight at present for the home apiary, such as yours."—G. M. DOOLITTLE, in *Gleanings in Bee-Culture*.

BEE=BOOKS

SENT POSTPAID BY

George W. York & Co.

Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, bound in the price in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated, with treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains full details of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared, perfectly according to Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. L. Root.—A cyclopedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 240 illustrations. It is written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honigerzeugung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cents.

Foul Brood Treatment, by Prof. F. R. Chesbire.—Its Cause and Prevention. Price, 10 cents.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Captions and Caponizing, by Dr. Sawyer, Fanny Field, and others. Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field. Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

1901—Bee-Keepers' Supplies!

We can furnish you with The A. L. Root's goods at wholesale or retail at their prices. We can save you freight, and ship promptly. Market price paid for honey, and for our best honey. M. H. HUNT & SON, Bell Branch, Wayne Co., Mich.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 15.—Choice white comb honey is arriving rather more freely and brings 15c. There is no accumulation at this writing, as receipts sell within a week after arriving, some of them on the same day. Amber grades bring about 12c. Extracted dull and slow of sale at anything over 50c. Beeswax, 50c. 2c. with good demand. R. A. BURNETT & Co.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are slow or less forced; lower prices from 1/2 to 1 cent per pound. C. H. W. WEBER.

BOSTON, June 24.—There is practically no comb honey in our market, and owing to warm weather very little call for it. Are expecting some new comb early next month. Market for extracted dull, at 1/2 to 3/4c. BLAKE, SCOTT & LEE.

OMAHA, May 1.—Comb honey, extra white, 24-frame cases, per case, \$3.40; No. 1, \$3.25; amber, \$3.00. PEYCKE BROS.

NEW YORK, July 8.—Our market is practically bare of comb honey, and demand good for white comb. Fancy stock sells readily at 15c; No. 1 white at from 13 to 14c, and amber at 11 to 12c. Extracted not in much demand, with plenty of supply; white, 60 to 65c; light amber, 55c; dark, 4 1/2 to 5c. Beeswax firm at 27c. HILDRETH & SEGELKEN.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts or stocks and little demand. It is between seasons now. Prospect of good crop in this vicinity from what bees there are left, the greater portion having been killed by foul brood exterminators. H. R. WRIGHT.

DETROIT, July 18.—Fancy white, 15c; No. 1, 13 to 14c; No. 2, 11 to 12c. Extracted, white, 60 to 70c; dark and amber, 55 to 60c. Beeswax, 26c. M. H. HUNT & SON.

BUFFALO, July 10.—No demand for honey yet unless a very small amount of fancy white at perhaps 15 to 16c. Some old lots still obtainable, almost, at 6, 8 and 10 cents. Beeswax, 22 to 25c. BATTERSON & Co.

KANSAS CITY, June 14.—Very little old honey on our market but what is damaged by being granulated. Sales are light at 15 cents for best grade No. 1 Colorado, Amber, 13c. Beeswax firm at 25 to 30c.

W. R. CROMWELL PRODUCE CO.,
Successors to C. C. Clemons & Co.

SAN FRANCISCO, June 19.—White comb, 11 1/2 to 12 1/2 cents; amber, 9 to 10c; dark, 6 to 8 cents. Extracted, white, 55 to 65c; light amber, 48 to 49c; amber, 35 to 40c. Beeswax, 26 to 28c.

Market shows no quotable improvement, but there are no large quantities (obtainable at the prices generally named by dealers). In a small way, for especially desirable quantities, slightly higher prices than are quoted are being realized.

Wanted Fancy White Comb Honey in no-drip cases; also Extracted white and state price delivered. We pay spot cash. FRED W. MITCH & Co., Front & Walnut Sts., Cincinnati, Ohio. Reference—German National Bank, Cincinnati.
25A17 Please mention the *Bee Journal*.

Wanted—Honey.

Car Lots or otherwise; will pay highest market price, spot cash. Address, stating quantity, quality, and price desired at your station. Will send man to receive when lot is large enough to justify.
THOS. C. STANLEY & SON,
314H FAIRFIELD, ILL.

Wanted.

Comb and Extracted Honey. Will buy your honey no matter what quantity. Will sample of extracted, state quality of comb honey, and price expected delivered in Cincinnati. I pay promptly on receipt of goods. Refer you to Brighton German National Bank.
C. H. W. WEBER.

More Bee-Keepers' Paradises....

E. R. Root has just returned from a 6,000-mile trip through some of the best bee-locations in the world, and has already begun his series of write-ups, accompanied with fine photos, in Gleanings in Bee-Culture. The following editorial appears Aug. 1, and will give something of an idea of what he will describe:

Some little time ago I promised to tell about the bee-keepers' paradise in Texas. I have this on the docket, and it will appear as I take up the line of my travels. But since running across that paradise I have run into two or three others. There is one west of the Rockies, in Colorado, that is not yet overstocked with bees or bee-keepers; another one in Central Idaho—in fact, I do not know but the whole State. These will be described in turn. The fact is, millions of capital are being invested in irrigation; irrigation means alfalfa; alfalfa means a paradise for bees. But I found all along my trip that alfalfa-growing preceded bee-keeping by two or three years, for it seems to take about that length of time before bee-keepers find these gold-mines that have been hitherto unoccupied.

If you are dissatisfied with your present location, and for financial reasons, or on account of health, will be compelled to leave, subscribe for Gleanings in Bee-Culture, and learn something about the great South and the great West. There are many locations in the West that are not yet occupied—splendid bee-locations. If you wish to learn about them, send 25 cents for a six-months' trial subscription, or \$1.00 for one year and one untested Italian queen. Or, send \$2.00 and we will send Gleanings one year and one of our celebrated Red Clover Queens.

☞ If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the base bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten those in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

HON. EUGENE SECOR, of Winnebago Co., Iowa, writing as July 25, said:

FRIEND YORK:—The past month has been unprecedently hot and dry. Bees loafing outside the hive to prevent combs melting.

The following lines express part of what we have endured in the last two weeks:

SOME JULY DAYS.

From out the burning east
 Comes dry Sol:

At God's first call
 He climbs the heavens to feast
 on withering corn and ripened grain,
 Turned yellow ere its time for lack of rain.

The lolling cattle seek
 The airy steep.

Or wade knee-deep
 In nearest friendly creek;
 The pastures, shorn and parched to brown,
 In vain appeal for the rain to come down.

The hot earth shrinks and cracks
 Beneath the glare.
 And men shun care
 As deer shun hunters' tracks.
 And every beast on bill or plain
 Is praying in animal language for rain.

Outside the hive the bees
 Are forced to rest
 To cool the nest.
 And wait for next frowsy trees
 And flowers to yield the dainty drop
 Which heat and drouth have caused to dry up.

No woodland song is heard
 From feathered throat—
 His wonted note
 Is dead within the bird;
 He pants and seeks the spring in vain—
 The fountain itself is thirsting for rain.

Thus wears the torrid day.
 The round, red sun
 His course has run.
 And no man bids him stay.
 For night is welcome since 'his plain
 Such days will never bring the longed-for rain.
 EUGENE SECOR.

MR. ELLIS E. MASON and Miss Anna E. Hirth, both of Toledo, Ohio, were married July 24, 1901. Mr. Mason is a son of Dr. A. B. Mason, secretary of the National Bee-Keepers' Association.

May long life and much happiness be theirs.

MR. HARRY S. HOWE, who has been known as Coggeshall's lightning operator, has been sick in Cuba, able to do almost nothing for two months, and the doctor says he will never be able to do any more hard work. The moral of which, says Editor Root, seems to be that it doesn't pay to work so hard. Let us earnestly hope that this time the doctor may be wrong in his prognosis.

MR. H. W. CORNELISON, of Washburn Co., Wis., has a very nice apiary, as is shown on the first page of this issue. The picture was taken from the northeast corner of the apiary looking to the southwest. The bees are located against the hillside, and the ground being rough Mr. C. has elevated some of the hives in order to level up and avoid washing by heavy rains. The row of posts in the middle row of hives were used to support poultry-netting. The trees in sight are butternuts,

and his bee-supply house is at the right, obscured by the trees. The hill sloping to the north affords protection from strong south and southwest winds, and a tight board-fence extends along the north side of the apiary.

Mr. Cornelison calls it "Summit Apiary," as the town is situated on one of the highest points in the State. The lake on the shore of which the village is located was formerly called "Summit Lake." It is about 3 by 4 miles in size.

"THE HOME CIRCLE."—A. I. Root quotes approvingly a passage written by "The Home Circle" of this journal, and says:

"There is one special point in the above that is worth noting. In any contest requiring the fullest development, both of nerves and muscles, and especially alertness as well as strength, the young man who does not use tobacco will, as a rule, come out ahead; expert cyclists learned this a long time ago; and in every department of business where a clear head and a cool, ripe judgment are required, the boy or man who lets stimulants alone has the advantage. Long live 'The Home Circle' in the American Bee Journal; and may Prof. Cook be spared for many years to conduct it."

MRS. JUDGE E. G. BRADFORD, of Newcastle Co., Del., is making quite a success of bee-keeping. A local newspaper, dated Aug. 2, says she has an apiary of 30 colonies, and that from one colony she took 140 pounds of honey recently. The other colonies were also in good condition, and promised an equally fine yield. Continued success to the "Mrs. Judge."

MR. A. I. ROOT, no doubt, to the delight of his old friends, perhaps forced into it by the absence of his son Ernest, has been giving considerable attention to the columns of Gleanings in Bee-Culture of late, and hence to the subject of bee-keeping. He seems to be skeptical as to the great difference in bees, and wants the experiment stations to tell us whether 40,000 bees in one hive gather more honey than 40,000 bees in another hive. If he will let enablers and posies alone long enough to give continued attention to bees, he will probably find that there is as much difference in them as in folks.

THE NATIONAL ASSOCIATION of bee-keepers is still growing in membership. Since our last report we have received the following names, and one dollar each:

JOHN SCHUEMAN, JAS. POINDEXTER,
 H. H. MOE, F. M. BRANDENBURG,
 W. W. WENROTT.

General Manager Secor, in a letter dated Aug. 6, says that the Association membership list "will crowd 1000 before September." That's good. Now, if only a lot more bee-keepers would feel sufficient interest to send in their dollars for dues, we would be glad to announce their names in this column.

We started out to get 200 members before the Buffalo meeting, which convenes Sept. 1—less than a month left yet in which to send in names and dollars. Why can't we receive an average of five or six per day from now on, and thus insure having an even 1000 members of the National Bee-Keepers' Association? It ought to be the largest and best organization of bee-keepers in the world. It will be if all who ought to be interested will step up and enroll their names on its honorable list.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

No. 33.

* Editorial. *

Shipping Comb Honey.—As the list of readers of the American Bee Journal is constantly increasing by the addition of new and inexperienced bee-keepers, it seems almost necessary to mention some things at least annually. One of the "things" is that of preparing comb honey for shipment.

All comb honey should be put up (we think) either in 12 or 24 pound single-tier cases, the former showing three sections through the 3-inch glass front, and the latter showing four.

After placing the sections in the cases with a follower back of the last row, and newspaper crowded in back of the follower, to act as a cushion, then put say a dozen of the 12-pound cases, or nine of the 24-pound, into a large crate. First, however, there should be several inches of straw put in the bottom of the crate to act as springs or cushion under the cases of honey, to insure safe handling.

It is best, also, to have say 1x3 inch boards nailed edgewise along the top of each side of the crate, and extending six or eight inches beyond the ends, to be used as handles by two men to enable them to carry it between them when loading or unloading.

Some firms send out the following directions to shippers of honey:

1. Put your name on the crate. *No name on crates.*
2. Put a caution card on each crate.
3. Put the gross weight, tare, and net weight on the front of glass side of each case before packing the honey in crates.
4. Put the total weight of all cases on the upper side of the crate, so this can be found without opening the crate.
5. Mark each case with the grade.
6. Mark each crate with the grade.
7. Put only one grade in a case.
8. Put only one grade in a crate, if possible.

Comb honey put up as above, should go safely anywhere with almost any kind of handling. It pays to prepare it properly, for it profits the bee-keeper nothing to produce a lot of nice comb honey and then have it broken and smashed in shipping, on account of careless or inadequate preparation for safe transportation.

The Building of Drone-Comb. The editor of the Bee-Keepers' Review deserves thanks for calling attention to an error in these columns which should not have occurred. He says:

Drone-comb is seldom built by a newly-hived swarm for the purpose of rearing

drones. As a rule, such comb is used for store-comb the first season. I mention this as I see an editorial in the American Bee Journal in which one objection urged against the use of starters in the brood-nest is that drone-comb is built, and, "as fast as it is built it will be more or less filled with drone-brood—generally more—and that brood is a waste." If frames furnished with starters are placed in the brood-nest of a colony just before it is ready to swarm, these frames will almost surely be filled with drone-comb, and the cells filled with drone-brood; but when a swarm is hived upon starters, no drone-comb will be built so long as the queen keeps pace with the comb-builders; but let the queen get behind, or go back to fill the cells from which the bees are hatching in the center of the brood-nest, and comb is then built to store honey in, it is quite likely to be store or drone comb; but it is very seldom that it will be filled with drone-brood at the time that it is built. By sorting over the combs in the fall the drone-comb can be taken out and used after that in the supers. Contrary to the belief of some, I believe that, under such conditions, combs are built at a profit even if they are to be melted into wax.

Mr. Hutchinson is quite right in saying that drone-comb when built *by a swarm* will not at once be filled with brood. The question, aside from that, whether it is advisable to allow such comb to be built, afterward to be cut out by the bee-keeper, is an open one. For one who has plenty of time for the work, and who *will do it*, the plan may be all right. It should be understood that it is possible to have all combs worker-combs without the use of foundation at all, and there may be some exceptional cases where labor and time are in so much greater supply than money to buy foundation that it may be economy to dispense with the latter. Given a lot of combs containing patches of drone-comb of greater or less size, it is certainly paying work to cut out all the drone-comb and replace it with patches of worker-comb. It is well, however, even for one who thinks it advisable to dispense with foundation, to take some pains to limit the amount of drone-comb built. It is usually practicable to do this by taking advantage of the fact that Mr. Hutchinson mentions, that so long as the laying of the queen in a swarm keeps pace with the building of comb there will be no drone-comb. Give a swarm on four or five frames, and little or no drone-comb will be built until these are filled. Then foundation or drawn combs may be given to fill the hive, or, if only starters, the drone-comb will be limited to these latter combs.

It is well to know, also, that nuclei or weak colonies may be depended upon almost surely to fill in holes with worker-comb, whereas if a patch of drone-comb is cut out of a brood-comb, and the comb returned to a full colony, the hole will be most likely to be filled again with drone-comb. The age of the queen makes a difference, the older the queen the

greater the inclination to build drone-comb, even a very weak colony with an old queen sometimes insisting on building drone-comb.

But when all the trouble and inconvenience of mending combs are taken into account, the number is very large to those who think it cheaper in the long run to forestall the actions of the bees by filling the frames with worker foundation.

Utilizing Cappings.—Efforts have been made at different times to get bees to use wax in building combs, the wax being furnished by the bee-keeper. Success has not always attended the efforts. E. Puffy now reports in the French journal, *Revue Internationale*, that he has had excellent success. He gives back cappings to the bees. The secret of getting the bees to use them lies in the honey between the layers of the cappings. It is essential that the cappings be not washed. Taken just as they come from the uncapping-knife, they are packed into a ball from the size of a walnut to the size of one's head, and put in the hive beside the feeder. Combs are then built out rapidly.

The Honey Crop of 1901.—Editor Root has been scanning the field, and concludes that bee-keepers need not be in haste to dispose of their crop for fear of glut. Even if the season were better than last year, there were fewer bees to gather it this year, especially in Southern California, where probably three-fourths of the bees have died through neglect or starvation, their discouraged owners thinking they could not afford to continue feeding them year after year. Elsewhere in general there is a falling off in bees, and he thinks prices should not fall below those of last season.

A significant fact is that the A. I. Root Co., which is one of the largest buyers of honey in small lots, has had no more honey offered this year than last. The well-informed bee-keeper will be in no hurry to sell his honey for less than it is worth. Editor Root says,

Let me give one interesting fact in this connection. The Root Co. finds it can buy honey from those who do not read bee-journals at a lower figure than from those who take one or more and keep track of the market. It is not our rule to set prices. We ask for a sample and the prices asked; and it is a fact that the *beekeepers* think to *cut out after a time a bee journal will sell his honey cheaper than he can get by paying for all the bee papers with his own bees.*

And yet there are people who say that bee-papers are of no value to them! Of course not, if they "know it all," or are too lazy or careless to read them, and profit by the information which the papers furnish.

Pear-Blight and Bees in California.

BY PROF. A. J. COOK.

THE relation of bees to the spread of pear-blight has become a very important question, not only in California, but everywhere in our country. For if there is any section where this microbe disease of the pear is not now in evidence, there is no knowing when it may break out. Thus a right or wrong position taken now, and defended and carried out, not only concerns California but every fruit-grower and every apiarist the country over.

The disease has existed in our country for many years. It was long a serious menace to pear-culture, in many sections, even before its nature and cause were known or even dreamed of. It usually commences early in the season, soon after the trees bloom, and first manifests itself in the dying back of the twigs. This continues till the whole tissue of the tree seems affected, as shown in the close, contracted bark on the trunk and main branches. The diseased tree is soon lost to usefulness, and is a centre for the spread of the disease to adjacent trees. All this was well known years ago. It was also known, as is generally true of microbe diseases, whether of plants or animals are the victims of their attack, that some kinds of pears and some trees seemed more susceptible to the encroachments of this foe than were others.

Some years ago Prof. Arthur, then, I think, connected with the Geneva, N. Y. Experiment Station, determined that there was a bacterial affection. He not only identified the specific microbe, if I remember correctly, but he inoculated trees at will, and always produced the malady. Prof. Arthur then suggested—though as I remember he did not prove it—that bees and other nectar-loving insects very likely carried the germs from affected to healthy trees; and that this was a probable cause of the rapid spread of the evil. This conjecture seemed more than plausible, for the rapid spread seemed to occur just after the time of bloom, and it would seem very probable that the active, tender stigma would be a good seed-bed for the germs. If these latter were in the nectar or the pollen, it would certainly be easy to convey them from diseased bloom to those that are yet exempt.

Prof. Burrill, of the Illinois University, who was first to discover and describe the microbe, did much to give us more knowledge of these bacteria of the pear.

More recently, Prof. Milton B. Waite, of the Department of Agriculture (the same who demonstrated that many varieties of pears are sterile to their own pollen, and must be cross-pollinated to bear fruit, and who recommended with emphasis that the honey-bee, as the most sure agent in this important and necessary work, be kept in the near precincts of the apiary, in large numbers) has given attention to this pear bacillus, known to science as *Bacillus amylovorus*, Burrill. He discovered it working freely and multiplying rapidly in the nectar of the flowers, and even collected the germs from the tongues of the bees, and, from these, started artificial cultures of the bacillus. His experiments seemed to show that while the microbes could be carried easily by insect or other flower-loving animal, it was of such a nature that it could not be carried easily, if at all, by wind. By carefully conducted experiments, covering the flowers, Prof. Waite seemed to show that nectar-loving animals, and not the wind, were almost exclusively the agents to spread this disease.

Prof. Milton B. Waite is assistant chief of the Department of Vegetable Physiology and Pathology, of the Department of Agriculture. That he is a very able authority goes without saying. While it is desirable that others confirm the conclusions of Prof. Waite—for in these domains of minute life the problems are too intricate and too complicated to be easily settled—yet there seems little probability that he is wrong.

Prof. H. B. Pierce, government pathologist, stationed at Santa Ana, Calif., has in some measure confirmed Prof. Waite's conclusions. He has investigated the pear-blight of Banning and Hanford, Calif., and proved it to be the genuine pear-blight of the East, and has, by inoculation, produced the disease. He is a very able, careful and con-

scientious worker in this field, and his opinion is very valuable. He accepts Prof. Waite's conclusions, and thinks that the reason that pear-blight in California acts differently from that of the East, is often taking a fresh start late in the season, is owing to the fact that the pear-tree here often blooms twice in the year, and thus affords the ready opportunity for its spread late as well as early in the year.

It has been argued that Prof. Waite is, or may be, wrong in his conclusions, as young trees in the nursery, which from age could not have borne blossoms, still suffer and die from this disease. We know that buds as well as bloom are tender and active in the early spring just as they are pushing forth. They also are covered with a glue which the bees gather for their propolis. These should be examined for the microbes. It is quite likely that they share with the bloom in furnishing a nidus and nutrient for the germs, and by luring the bees may also be active instruments in the fatal spread of the germs.

WHAT SHALL WE DO, THEN?

The bee-keepers of the great San Joaquin Valley have agreed to remove their bees in the time of orchard-bloom. I am glad of this, for it shows that they are ready and willing to do the right thing. But is this the wise thing? There are myriads of other insects, as also many colonies of escaped bees, that can not be removed. Were it not true, the pears would not be pollinated, and, as Prof. Waite has also shown, these are necessary to a crop. Better the trees go, than to cumber the ground in fruitless state. These being present, the removal of the apiaries will not remove the evil. Their removal will soon demonstrate this when the fruit-men, who are so desirous to be fair and just as are the bee-keepers, will ask that the latter be left undisturbed.

While I feel sure that we need apiaries near large orchards to cross-pollinate the bloom properly, and thus aid to secure a full crop, I am just as sure that there are quite enough other little nectar-loving insects, to scatter the disease. Pollination must be wholesale; only a few inoculations per tree are necessary to work the havoc. Thus while removal of the bees will interfere with the crop, it will not materially check the spread of the dread disease.

I believe it will be a more sure remedy to try to breed pears that are immune, as Prof. Pierce is doing with the walnut. This will insure trees that are invulnerable, will leave the bee-keepers undisturbed, and will preserve to the orchardists the bees, which, in their grand work of cross-pollinating the bloom, are invaluable aids in all successful agriculture.

Los Angeles Co., Calif.

Rendering Combs—A Method of Doing It.

BY ADRIAN GETAZ.

DURING my thirteen or fourteen years of bee-keeping, I had my old combs, drone-comb cut out, combs (I must say to my shame) more or less eaten by the moths, and full of webs, etc., accumulate until something must be done. Some two or three years ago, I rendered by the ordinary process, all that could be advantageously treated so, and made comb-foundation out of it with the help of a home-made cement mold. A full description of the process was given at the time in the American Bee Journal.

But I had yet some of the worst combs and some of the refuse of the melting of others. And here let me tell you that the moth-eaten combs are the very meanest thing to deal with that can be found in that line. I did not want to go into much expense, as the wax to be obtained was not worth very much; at least I thought so, but I got considerably more than I expected.

All the materials needed to construct the apparatus I used, were an old tin bucket, a piece of old tin to make an outside jacket to confine the heat of the oil-stove around the bucket, some scraps of wire and strong galvanized iron, a scrap or piece of wire netting, and some nails in place of rivets.

While on the subject, it may be well to say that wire nails heated red hot, and then slowly cooled, become soft enough to make excellent rivets. I had the oil-stove already.

If you melt some combs in a receptacle of any kind with a quantity of water, and let it cool, and then investigate carefully, you will see that the wax has come entirely above the water, being lighter. The refuse, cocoons, moth-webs, etc., being somewhat lighter than water, form a mass

partly above the water-line, and partly below, something like this:

I said that below the water-line there would not be any wax. That is true only when by sufficient stirring and boiling the wax has had the chance, or rather the time, to disentangle itself entirely from the refuse. Now when the quantity of wax is considerably larger than the amount of refuse, all that needs be done is to take the cake out and scrape off the under part composed of wax and refuse mixed. The scrapings can be added to the next melting.

But when the amount of refuse is considerable, there is not enough wax to rise over the refuse, and the cake you take up is a mixture of refuse and wax. The problem was how to keep all the refuse under the water-line. I first melted the combs in the tin bucket with water enough to fill it about two-thirds, stirring and boiling long enough to disaggregate the combs entirely. I then put in the sieve made of wire-netting re-enforced by bands of galvanized iron, and fastened it there. Then I added enough boiling water to bring the wax entirely above the sieve, and let the whole boil long enough to give all the wax time to come through the netting. When cold it is something like this:

Some of the finest refuse came through the netting, but not enough to be objectionable.

One difficulty I met. I had to boil the whole thing quite a time in order to get all the wax to rise. After thinking about it, I concluded that by adding a considerable quantity of salt to the water the wax would rise much quicker. And it did.

Somebody may want to know how that can be. Why does the wax come on the top of the water? It is because the wax is comparatively lighter than water. That difference of weight is the *force* that *pushes* the wax above the water. That force amounts to about 3-100 of the actual weight. That is, if a vessel full of water contains 100 ounces of it, the same full of wax will contain about 97 ounces of wax. And as I said, that slight difference of weights—*three one-hundredths* only—is the *force* that pushes the wax above the water.

Now let us add, say one pound of salt to the gallon of water. The volume of the water will not be increased, but its weight will be increased by about 12 percent. That is, the same vessel which contained 100 ounces of pure water will now contain 112 ounces of salted water. The difference between the comparative weight of the water and the wax will now be 15-100 of its weight, instead of 3-100, that is, five times greater.

And the *force* that pushes the wax above the water will also increase in proportion, and be five times greater with the salted water.

Do you wonder now if the wax does actually rise faster when melted in salt water? Knox Co., Tenn.

The Premiums offered this week are well worth working for. Look at them.

Cheap Packages for Extracted Honey.

BY C. DAVENPORT.

IN a previous article I mentioned that I expected to be able to use for retail trade, a package for extracted honey that, aside from the work of preparing it, would cost only about half a cent for a package holding a few pounds. At that time I did not intend to say anything more in regard to the matter until I had experimented with, or tried, the package in a larger way, for as yet the whole matter is in the experimental stage with me, as it was too late in the season, or rather, my extracted honey was nearly all sold last season before I thought about using these packages. Upon reflection, I have, however, decided to tell what I know in regard to the matter in the hope that it will lead others to experiment in this line.

Possibly I have already solved the most important part of the problem, or perhaps upon further trial in a larger way some serious defects may be found about it. As the reader has probably surmised, these packages are paper sacks, and probably many who read this know that a heavy grade of tough glazed manilla paper will hold, or resist the action of, honey almost as well as tin will, for how long a time I am unable to say, though the grade or kind of paper used would have much to do with this, for there are a good many kinds of paper called "manilla," many of which are entirely worthless for this purpose, and if the paper of which the sacks are made will not itself hold honey, I have found that these poor grades of glazed manilla paper are inferior for being waxed, to hold honey, to other grades or kinds of paper that are not glazed.

So far as I have gone at present I believe that if the sacks are to be waxed they are better if made out of tough, unglazed paper that is slightly porous. Such paper will, when waxed, resist the action of honey for some time; again, I am unable to say how long, but certainly long enough to serve for a retail package to the producer who delivers direct to the consumer.

Whether it can ever be perfected so that it will answer for the retail grocery trade, I am unable to say, but I have hopes that it will; but whether this occurs or not, these packages will, in the near future, in my opinion, be used largely, and answer a most useful purpose to producers who retail in small amounts, and have, as I have, a large class of customers who are so frugal and economical that they will not buy a glass or tin package, and seldom return one lent them.

Whether paraffine would answer in place of wax is another thing I do not know, for I had none on hand last fall. If it would, besides being cheaper its color would make a more attractive and inviting looking package, though a waxed sack is not defective in this respect, and it is a clean sanitary package. Perhaps a mixture of, or preparation of, both wax and paraffine might answer better than either alone. A small amount of rosin might also be a benefit. There is room for much experiment in this respect, and I hope that all others who experiment in this or any other way in regard to the matter will report results, whether favorable or otherwise, for it would no doubt be of interest to many besides myself. I do not have the time to do but a very small amount of the experiment work about many things in regard to our pursuit that I should very much like to do, but I shall this season try these sacks in a larger way than I did last year. I have little doubt but what they will, with me, solve a perplexing problem.

When using them, if the honey is delivered, all that would be necessary to insure their safe carrying would be to pack, or lay, the filled sacks in a large tin can or case, that has a tight cover to exclude dust. The sacks can be tied up and then wrapped and tied up in another piece of paper, on which has been written the number of pounds, and who the package is for. A large number of these sacks could be laid in one large can, and handed out as handily as any package. But with customers that come to the apiary it would not do simply to tie a sack up in paper this way, for in many cases, unless care was used, it would be torn, or get a hole in it, and allow the honey to escape. This, besides raising a howl of disgust and protest from customers, would not answer, for we would surely lose trade if we furnished a package that failed to carry safely.

To overcome this would be quite easy. I have not tried it except in a limited way, but I have no fears whatever that this part of the system will work all right in every way. All that is necessary is to make an outer package or covering from strong cardboard, or what is called "building paper" is what I used; this is about like cardboard or pasteboard, but instead of being stiff or brittle like the

former, it is pliable and can be bent in any shape without breaking. This was cut into shape on about the same principle as all folding cardboard boxes, only one side has to be glued. The ends are cut to fold together, and are held in place after the sack of honey is put in, by strings around the packages. This outer covering or case makes it practically as safe to carry honey in a paper sack as in a tin pail or stone jar—perhaps safer, for with either of the latter the honey is lost if it is tipped over.

Probably most of those who read my first article on this subject smiled incredibly when I said that possibly extracted honey might be shipped in sacks, but I have not much doubt but what it can be done. What will you give me, Mr. Editor, for honey shipped in sacks, I to guarantee that it reaches you in good condition, without leakage occurring for one month after you receive it? Make me a good offer. In after years, if most of the extracted honey should be shipped this way, it might be quite an honor for you to be able to say that you were the first one to buy in sacks; and, for me, that I was the first to ship it in this form. If I had only thought last fall when I had the honey in those large sacks, to find out how much of a jar and rough handling they would stand, I should know something more definite about whether it could be shipped safely in sacks. It would have been an easy matter to find out what a sack could stand, by taking one and raising it up and dropping it down at different heights inside a large can or barrel until it would burst. Perhaps those would have stood as much in this line as tin would—possibly more. Or, if those I had in use were defective in this respect, it might be, and is, by no means improbable that sacks might be made of material that would stand as much, or more, strain and rough handling than a 60-pound tin can. Then all that would be necessary to insure safe shipment would be to use wooden cases, the same as with tins, and pack two or three inches of clean straw or hay all around between the case and sack.

The object in using sacks, it is probably needless for me to say, would be the very great saving in the cost of the package. Probably at least two dozen 60-pound sacks could be sold for the price of one 60-pound tin can. And the saving in freight would also be great. The empty sacks could be rolled up and shipped to the producer, and the freight on enough to hold many thousand pounds would be but a few cents. And if one did not wish to make his own cases, they could be shipped in the flat for less than half what they can be nailed up.

What about candying? some may ask. In regard to this I have only space enough left to say that I have liquefied candied honey in paper sacks.

Southern Minnesota.

[We are not quite ready yet to order shipments of honey in paper sacks, and thus get honor unto ourselves! But some day it may be just the thing.—EDITOR.]

No. 5.—Some Reminiscences of an Old Bee-keeper.

BY THADDEUS SMITH.

I HAVE been in the habit of making such frequent visits to "My Old Kentucky Home" that I hardly feel that I have lost my citizenship there, and I have not forgotten or lost my interest in her citizens, especially those who may be classed as belonging to a former generation; and as I purpose to notice some cotemporary bee-keepers of 30 years ago, in whom I felt most interest, it is but natural that I should call up the Kentuckians first.

My neighbors, Dr. John Dillard, and Mr. D. Burbank, of Lexington, and Prof. R. A. Broadhurst, principal of the Kentucky Female Orphan School at Midway, were intelligent, enthusiastic bee-keepers, well informed in the science as far as it was then developed; and so was Mr. Nesbit, of Cythiana, and Mr. G. B. Long, of Hopkinsville. But these did not keep themselves very prominent before the bee-keeping public by frequent communication to the bee-papers, because they had no "ax to grind" in the sale of patent hives or Italian queens.

The most clever writer and original inventor of that State was Mr. D. L. Adair, of Hawesville, who contributed many interesting and instructive articles to the columns of the old American Bee Journal when published in Washington, D. C. Mr. Adair had originality with a bright, investigating mind, well stored, and a fluent, agreeable way of expressing his ideas; but some of his ideas and conclu-

sions were peculiar. For instance, he held that bees could live, if not indefinitely, yet for a long time, without admission of fresh air to their compartment—that they could be sealed up tight in a box, and they would live and remain perfectly quiet without injury for a number of days. I do not remember the limit of time he gave to their confinement, or how long they would continue satisfied thus excluded from fresh air. It was a singular position to take, yet from the facts he gave and his plausible reasoning, one could hardly dissent from his conclusions. I would like to know if others have observed this fact, or if the theory has ever been thoroughly tested and confirmed, or exploded.

Mr. Adair was the inventor of an original controllable movable-comb hive, quite different in principle from Mr. Langstroth's hive, or from the hives of Mr. Langstroth' many imitators. His hive was composed of a number of sections, put together side by side and held in place by a simple and ingenious device. These sections were made of thin stuff, just as wide as the width of a comb and the space between combs together, and a triangular comb-guide placed in each, and when put together formed a box, or the hive proper—using boards for the ends. The sections were about the size of a Langstroth frame, being somewhat deeper and shorter, and could be taken apart easily, and each comb separated from the other and examined—the size of the hive depending upon the number of sections used. Sections were placed at each end for surplus, either for extracting or for comb honey in sections; and thus I think originated the "long ideal hive," or the long hive with side-storing surplus arrangement. As this section hive was made of thin material, an outer receptacle had to be provided for its protection; and these were made of wood, brick, stone or cement, of such a size as would hold the section hive with its surplus receptacles, that were shoved into it through a door in the rear, and had to be withdrawn for examination.

I once made an Adair hive. It looked all right, but somehow I never had the courage to put a swarm of bees into it. It remained in my honey-room for a number of years, and I kept thinking I would try a colony in it, but I never did. In comparison with the Langstroth-Simplicity, and with Smith's "Quinquelplex-Duplex-Combination, etc., hive," it seemed too much other.

I think Mr. Adair really believed, at that time, that his hive possessed advantages over the Langstroth, and other frame hives. Hundreds of his hives were used in Kentucky and Tennessee, but I doubt if any one uses them now by preference.

So far as I know, Mr. Adair should have the credit of inventor, or original user, of the section honey-box. He used sections for surplus both on the sides and top of his brood-chamber. His section-boxes, no doubt, differed in size and finish from the beautiful, polished white-wood sections now in use, but they involved the same principle, and it was probably from them that the sections of to-day were evolved.

Mr. Will R. King, of Franklin, Ky., was a hive patentee, or a vender of a patent hive, that he called "The Triumph Hive," and an Italian queen-breeder. He took every opportunity to call attention to and advertise his wares through the reading columns of the American Bee Journal, with which he claims that he has succeeded in having queens fertilized in confinement, and the general way he had of pushing his business, made me strongly suspect him of being a Yankee. However, I do not believe he was any kin to H. A. King, of New York, the hive-man who disputed and contested Mr. Langstroth's claims so strenuously, and, as some thought, not honorably.

As far back as 1872, W. R. King claimed that he had succeeded in having queens fertilized in confinement, by having the queen and drones fly in a tent, excluding all workers from it, and he gave a detailed account of the construction of his tent and process in the old American Bee Journal of that date. The plan and principle involved is the same as that of Mr. Davette, that has lately been resurrected and given a prominent place in several bee-papers. The point strongly emphasized by Mr. King was that all worker-bees should be kept out of the tent, and the queen and drones must never have been outside their hive before set to flying in the tent. He accomplished this in a different way from the plan of Mr. Davette, and I should judge that Mr. Davette's way is the best, but they both acted on the same principle—"keep the workers out."

Thirty years ago, when the country was full of black bees and comparatively few Italians, there was great difficulty in getting Italian queens purely mated, and the subject of controlling fertilization was an important one for

the numerous queen-breeders that then sprung up all over the country, and hence many were led to experiment to get queens mated within the hive, or in some other enclosure where they could meet only selected drones. A number of persons claimed that they had succeeded in getting queens mated within the hive, and also in a tent with just such drones as they selected. But the more reliable apiarian teachers did not come forward to endorse these claims, and the general bee-keeping public were slow to believe that the thing had ever been done. As the Italians increased in the country, and the blacks decreased in proportion, there was not so much danger of queens mating with black drones, and as to prevent this was then the only object of seeking fertilization in confinement, the subject was not considered of so much importance. Although Mr. King claimed success with his tent, he said as far back as 1872, that he would not use his tent the next year, as the place where he intended to rear queens had but a few colonies of black bees in the neighborhood, and these few he intended to Italianize, and he would not consider it necessary to take his tent with him.

Thus the matter has been suffered to lie dormant these many years, until Mr. Hutchinson heard of Mr. Davette and his tent, and published an account of it a few months ago. It is now considered that the Italian bee itself, and probably all other races of bees, can be improved in their honey-getting qualities, and in their dispositions, by select breeding; and it is claimed that much has already been done in improvement of the Italians by selection of queens only, and it is believed that much greater improvements could be made if the drones could be selected also. Hence the new interest now found in this old subject of fertilizing queens in confinement with select drones. It is to be hoped that the thing will be fully and fairly tested, and all doubt removed from the possibility, or else the whole thing condemned as impracticable.

Mr. R. M. Argo was another intelligent Kentucky bee-keeper, who sometimes gave us the benefit of his knowledge through the columns of the American Bee Journal; but I have not seen his name or that of any of the others in the papers lately, and I don't know how many of them are still alive.

The End.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Requeening an Aply Now.

Would it be of any use to requeen my colonies at this time? Would they produce any more honey? Some of the old colonies are loafing around in a listless manner, while the new swarms are working full time? PENN.

ANSWER.—It depends upon circumstances. If you requeen with better stock it would be a good thing. It is very advisable for you to keep a close record of the work of your colonies, and try to have queens in all the colonies from those that have done the best work.

Getting Bees Into the Sections—Uniting Colonies, Etc.

1. How late in the summer do bees build comb? Is there any particular time for them to cease building?

2. I took some honey from some of my colonies in June, and they have not replaced the comb or rebuilt anything. What is the reason?

3. My bees don't seem to take to the supers that have one-pound sections in them, where they had starters, etc. Would it be any inducement to remove everything above the brood-chamber but the super with the one-pound sections? or would a super of shallow frames filled with honey and merely left on the hive till wanted for use, cause the bees to go into the pound sections to work, giving them that much more to cover and care for?

4. Would it be a practical and successful way of unit-

ing two weak colonies, each having a queen, to put one hive over the other, placing a piece of wire netting between for a day or night, and then let them regulate which queen they shall retain?

5. Is there any way of telling when a colony has lost its queen and is growing weak, without going into the hive to examine?

6. Can the presence of the moth-worms be known without opening the hive to examine for them?

MISSISSIPPI.

ANSWERS.—1. The most of the building is done during harvest-time, but there is no particular time for them to begin or quit. They will build comb whenever needed, in rare cases even in quite cool weather.

2. The probability is that no honey was coming in, and they felt no necessity for filling the vacancy.

3. What you say in the previous question makes it probable that no honey was coming in, in which case they would not do anything in sections. If there was a super of shallow frames on top, those frames being partly filled with honey, the bees would not so readily enter the sections unless they got more honey than they could easily store in the shallow frames. In the same way, if a super of sections partly filled were on the hive, they would not touch another super of empty sections. But if you remove the super of shallow frames, the bees will begin on the empty sections sooner than if the frames had not previously been there, always providing any honey is coming in.

4. It will be likely to work all right, but you will be safer against fighting if you remove one of the queens a day or two in advance. There must be an entrance to both upper and lower hives.

5. Not for certain.

6. Not certainly. If you see worms dragged out, you will know, but you don't always see that.

Late Wax-Secretion and Laying—Killing Drones.

1. How late in the fall can bees make wax?

2. How late does the queen lay eggs?

3. Is it profitable to kill the drones now, when we want no more swarms? ILLINOIS.

ANSWERS.—1. Very late if it is necessary, although there is generally no occasion for it. I think bees might be forced to secrete wax in the middle of winter.

2. The time varies greatly. A queen may stop laying in September, or she may continue till frost. Much depends upon the yield of nectar. Sometimes queens continue to lay although no brood is reared. It is a more common thing than is generally supposed, to find eggs and sealed brood in the hive, but no unsealed brood. The queen keeps on laying, but the bees do not take care of the eggs; perhaps eat them. My place is in the region that suffered so terribly from the July drouth, and brood-rearing was almost entirely suspended, although the queens continued to lay. In some hives were found neither sealed nor unsealed brood, although eggs were always present. If I had been a better bee-keeper, I suppose I would have fed to keep up brood-rearing (it did later on), but I had never had such an experience before, and was expecting a change every day.

3. Yes.

A Beginner's Bunch of Questions.

1. I use the 8-frame hive. I have only eight colonies of bees, having bought five last spring, all Italians. I had two hybrid colonies. Now there are four hybrids. Is there any way to keep them from mixing or becoming hybrids?

2. Can I breed them back and make them all Italians again? If so, how?

3. I haven't had any swarms issue yet. They are all strong, and working well. What is the cause of their not swarming?

4. What is the best time of day to "rob" the bees?

5. I would like to increase my colonies to 15 or 20. As they will not swarm, what and how shall I do? Is it too late now to transfer? The cotton-bloom here is our main honey crop.

6. What is the best way to catch the queen and handle her without hurting her?

7. How many colonies can one man attend to?

8. How much honey is it expected that a strong colony will store in one season? TEXAS.

ANSWERS.—1. So long as there are black or hybrid bees within two or three miles of you, the likelihood is that most

of your colonies will be of mixed blood. Rear from pure stock each year, and eventually you may work out the black blood.

2. As in the previous answer, your most hopeful plan is to breed your queens from pure stock, and when you run out of pure stock get a pure queen. A careful study of your text-book may be of some help.

3. Hard to tell. Possibly they are not getting enough honey.

4. Right in the heat of the day, when the bees are busy at work. If there is danger of robbing, however, it may be better to take away the honey in the after part of the day, so that darkness may cover any tendency to robbing.

5. It is difficult to advise just what is the best way for you. If you will carefully study your text-book you will probably be better able to judge for yourself. One way is to take all but one frame from the hive and put them in a new hive on a new stand. Leave the queen on the old stand. Let all the adhering bees be taken with about half the frames, and shake off into the old hive the bees from the other half. It is not too late to transfer.

6. Catch her by the wings or by the thorax (what, perhaps, you would call the shoulder)—never by the back part or abdomen.

7. Probably five colonies are as many as would be wise for you to have till you gain some experience. An experienced bee-keeper may care for 100 colonies or more.

8. Very often more is expected than realized. There is no definite amount. It may run from nothing to 200 pounds or more. If you average 50 pounds you need not complain.

Importance of Pure Drones.

Is it not a fact that our bees ought to have three distinct bands to show their purity? If so, I want to know why our drones from the same mother are not purely marked? While bees and queens are purely marked our drones are not. What I mean by that is this: We have some drones that are black, and some of these are yellow-banded, which I believe shows impurity. If this is not impurity, I do not know what you call it. In breeding bees I do think the drones are the ones we ought to be particular about. I think if we can get our bees, queens and drones all with the same marking, we will have better bees and more honey, as my experience of about 20 years with bees has shown.

TEXAS.

ANSWER.—You are right in thinking that there should be uniform markings in the drones of pure stock, and also that it is just as important to have good drones as good queens to breed from. One reason, and perhaps the only reason, that so little attention is paid to the drones, is the difficulty of controlling the mating. But that is not a sufficient excuse for neglecting what can be done in the way of suppressing poor drones and encouraging good ones.

Replacing a Drone-Layer.

I had a colony of bees in my apiary with crooked combs, and I cut them out and straightened them. The bees had swarmed some time before. I found that the capped brood was raised, and also some of the cells had two and three eggs, and some had none, so I looked up the queen and stuck a pin through her, and then gave them some brood from another hive for rearing a queen. Was it right to give them the brood at that time, or should I have waited some time and then cut out queen-cells, and then give them fresh brood?

IDAHO.

ANSWER.—It is not likely that you would have gained anything by delay, but would have lost. It would have been just so much loss of time, the colony meanwhile becoming weaker, the bees older and less fitted for rearing a young queen.

Brood-Chamber Crowded With Honey, Etc.

1. I have a colony of bees whose queen was old, and let them store honey in the brood-nest. I have requenched, but the new queen has little or no place to lay in. How can I make the bees remove the honey from the brood-nest?

2. Has not the Danzenbaker reversible frame this advantage, that as the bees will not allow honey at the bottom of the frame, when you reverse it you force them to store it in the supers?

3. Can you tell me if we have a fall flow in Minnesota? There are no buckwheat fields near.

4. My bees worked on lilacs this spring. It this usual? MINNESOTA.

ANSWERS.—1. You can hasten the matter by uncapping the honey where you want the queen to lay. All the better if you do not make a very smooth job of it. One way is to take a saw, or a piece of a saw-blade, and scrape the surface.

2. At one time much was made of this feature of the Danzy and other reversible frames. I don't know whether it is now much valued.

3. I think in most parts of Minnesota there is more or less of a fall flow.

4. I think it is not unusual for bees to work on lilacs, but the number of lilac bushes is never large enough to make the plant an important honey-plant.

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

GARDENS FOR THE CHILDREN.

Aunt page 409, where Prof. Cook talks of a garden for each child, there are two children at the home in which I live. They were fond of planting things, but seemed to manifest almost idiosyncrasy to the details of the matter. Surely, I thought, it would be no use to give them gardens. Well, this summer their father took it into his head to do just that. And he didn't give them little and worthless bits, either, but large plots of very fertile ground. The result is that with a very moderate amount of advice and assistance they are having some success. Their crop will not total much in money; but when we come to consider things worth more than money, no equal area of the farm will produce so much. Had the plots been smaller, so as not to oversize the amount of hoeing they enjoy doing, it would have been a little better.

A HOUSE-CELLAR FOR BEES.

Some have doubted whether a house-cellar, with footsteps and children's play immediately over the bees, could be anything else than a very poor place to winter bees in. As a counterblast to this it is interesting to see that the Gleanings cellar, with machinery overhead, proved a first-rate place. The fact seems to be that bees will get used to almost anything if it is only experienced hourly or very frequently; but when noise or jar occur irregularly, and not much oftener than once a week, then they are disturbed and injured. Page 413.

QUEEN FERTILIZING EGGS.

F. Greiner may be right, page 420, that the queen fertilizes eggs, or omits to do so, entirely without volition. Something other than space, or curvature of the queen's body, may deftly produce effects. I opine, however, that a "straw vote" would show him badly in the minority.

"JOUNCING" EXTRACTING-SUPERS.

I don't want to make sport of any manipulation which a practical brother finds to succeed even tolerably well. If I did I might try to be funny over Mr. Davenport's method of jouncing out the bees of an extracting-super. I'll be respectful; but I'll wait till a lot more of the brothers find it a success before I jounce. Page 420.

SWARMS GOING BACK.

Tell Dr. Miller, page 425, that among Ohio bees more than two swarms go back to the old hive after flying, for each 98 that go to the woods. Of unmixed swarms, with laying queens, and the queen all right, perhaps his proportion would answer. Swarming and going back into the old hive again has been abnormally in fashion the present year—going back before clustering, and going back after clustering, and going back during attempt to hive, and going back after having—all sorts of going back. When bees from different hives get mixed in swarming (a very common thing in a large apiary with swarm-fever raging) the queen or queens will often be balled—at least half the time if the bees are light of honey—which is also a common thing, at least in this yard. The little ball of bees and queen often falls from the cluster to the

ground, and is liable to be left unnoticed. Then, of course, the queenless bees go home, either before or after hiving. Sometimes the ball is formed after hiving, or deposited with the rest of the bees at the door of the hive, and carelessly left there when they run in. In these cases also the bees go back to the old hive—never to the woods, I think. While we are on the subject of swarming let me "swat" another old and popular fallacy—the idea that bees load up with honey preparatory to starting out. They go just as they happen to be. I am pretty well convinced. A swarm imprisoned will sometimes quickly begin to die of starvation. On the other hand, after three days and two nights of imprisonment, they will often be found with a good piece of comb built and honey in it. This imprisonment trick is a hobby of mine, and thus I know.

WINTERING OF DIFFERENT STRAINS OF BEES.

I suspect it is easy to be mistaken when we say that one kind of bees winters better than another. In a mild climate, however, which may happen nevertheless to be a climate in which staying quietly indoors is much more profitable than hustling around, it is reasonable to expect that blacks might winter better than Italians. But, Mr. Whitcomb, mightn't a poor and lazy strain of Italians idle and prosper just as well as blacks could do? Might not prosper as well next June, eh? Then I guess you're pretty much altogether right. Your fourth point is hardly important enough to rank with such important things as the first three points comprise, Page 428.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

STRAWS POINT THE WIND.

We all court or desire popularity. Few of us get it in as generous proportions as we would desire. We all have among our friends those whom we not only love and admire, but who are general favorites. Everybody is quick to take them up, and even more slow to let them slide out of their social circle. I have often thought, and as frequently said, that no fortune could be justly said to out-rank that of having for our life's work that which we enjoyed most to do. It is almost as beneficent and helpful to be attended in our life-journey by those who admire, respect and love us, and who are ready to trust us to the full, for they know us, and the knowledge has begotten faith. I know of no single thing that gives such full satisfaction as the sure thought that those who know us best believe in us. There is no show of wavering in their faith.

We all have known public men whose presence among their neighbors and friends is sure to bring loud acclaim. They are ever greeted by their constituents with loud and heartfelt cheers. All this is most grateful to him who is so happy as to receive it, and must be a most potent influence, not only in making the life more pleasurable but also in causing it to yield richer and more abundant fruit.

No great factor in the happiness and success of our lives is well-earned popularity, that we are all wise to study the ways and lives of our most esteemed friends, that we may, if possible, discover what attracts and wins, and then may strive with unflinching effort to crown our own lives with like virtues. Camp-life furnishes most excellent opportunity for such study. The "straws which point the wind" are ever in evidence.

We are in camp. Many other campers are near neighbors. The meals are to be provided; the wood chopped; the dishes washed; the camp to be kept neat and tidy; not only our friends but others who have not such evident claim on us, are, or ought to be, entertained. The books brought to camp are very entertaining; the many magazines abound with fascinating recitals or stories; special friends are so attractive; how much there is to make selfishness assertive, how many straws will show the trend of character. Here is where the one who has grown into a life of thoughtfulness for others shines forth as the noonday sun. Such a one takes no heed to find the exact bounds of his allotted tasks, but is ever reaching out with helpful hand to lessen the burdens of every other one. He is quick to lay aside the entrancing story to help some other in a wearying task, or to entertain some older person, or, possibly, some visitor who has come to the camp for recreation which the home camp has failed to furnish.

Some one in camp has been off on a long tramp, climbing the ever-alluring mountains, or seeking some pool where the trout are more quick to bite. He returns weary, and, oh! so hungry. Yet his it is to see that the meal is prepared, or the wood chopped, or the dishes washed. The dragging step and tell-tale pallor are quickly noted, and he finds his work is snatched from his tired hands, by those more than eager and willing to do it for him. This straw of thoughtful unselfishness is a very jumbo, and tells a whole chapter of character trend, which ever charms, wins, and sweetens. If one ever gets just "dead tired" and "dead gone" with hunger, it is on the long tramps along the mountain streams of the deep, wooded canyons, or climbing the steep mountains, where lured on by beauty and awful grandeur the tramp carries us often away beyond our strength, and yet we must retrace our whole rugged journey before either rest or food—possibly before water—can bring the longed-for refreshment.

Here is where the Mark Tapleys shine out.

Here is another colossal straw. Some so thoroughly hold themselves in fullest control, that they "burn all their own smoke." Tired, used up, every bone and joint crying out with the hard ache of sorrest exhaustion, yet we hear not a word of murmur; indeed, they have still cheer and sunshine for others who seemingly are more weary than are they. Surely, these are heroes that see no battle-field, and whose praises are all unsung on History's page. Yet camp-life shows their status. "Straws point the wind."

"OLD BALDY" (San Antonio Mountain).

Where is it? and what? It is one of the three highest peaks of the Southern California mountains. It reaches up 10,000 feet, and lies 23 miles north from Claremont. It is 16 miles west of our camp, which is something over 3,000 feet above the sea-level. Seven of us scaled it on Monday last, three of whom were ladies. Horses or mules, and one pack-mule, carried us and our belongings 12 of the 16 miles. Then we must walk and carry our food and blankets, for we must sleep that night on the very crown of the lofty summit. What a climb—1000 feet, or 1000 feet to the mile! Two and one-half miles more on the very ridge-pole of a great roof-like mass of granite—a mere narrow path often hardly a foot wide, and steeper on each side than steepest roofs; often almost perpendicular on one side, reaching down more than 1000 feet—more than one-fifth of a mile. Often this path stretched upward as fast as onward, and yet our party flinched not, but all slept that night on the very crest of this grand mountain peak. Only one took to hands and knees, and she but once. But more than one wondered if they could do it. And almost all drew long breaths as the most trying points were scaled. So rare was the air that ever and anon all would pause to draw a half dozen quick breaths in rapid succession, before the onward march could be resumed.

It was a tremendous climb but the outcome warranted the labor, the fatigue, the tremor of fright, for the outlook from the crest, as also the sunrise, were entirely indescribable. If one ever seems right in God's very presence it is while on some such towering peak as "Old Baldy." As I gazed entranced at the grand, varied, far-reaching landscape, I uttered the truth that I would rather have given \$25 than to have had my daughter miss the experiences. She made the trip with easy, lightsome steps, and hardly knew her weakness till the race was run. Our beds were on the small broken rocks that mark the bald summit; with a good camp-fire and our blankets we kept the chill away, and slept some.

At 5 a. m. we enjoyed the transcendent sunrise, which alone paid for the journey. We then proceeded at once to make the home-ward march. We reached camp at 12:30. Oh, we were so tired! All our party kept their cheer, their smiles, and their tempers. I gazed all by my own tired muscles, and was proud that I had such friends and comrades. Those light of weight, and used to labor, endured it well; those great with avoirdupois, and unused to such exercise, almost fainted on the home stretch. Yet we all have even now lost sight of the hard effort and wearisome climb, and now think only of the beauty and grandeur.

We seemed, and will ever seem, nearer to God, for we were a hand and a day in the very glory of his most magnificent handiwork.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical book-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last.

To Our Shippers :

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "HILDRETH, McCaul Co.," and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name HILDRETH in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract :

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120-122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs: it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are hereby restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the defendant at No. 120-122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of "Hildreth" separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDRETH & SEGELKEN,

265-267 Greenwich Street, NEW YORK, N. Y.

Is the "Wide-Open" Fair a Financial Success?

The Civic Committee of Boston has sent a series of questions to the secretaries of all the State Boards of Agriculture, asking whether, in their opinion, the "purely legitimate Agricultural fair or the "wide-open" fair pays better in the long run financially, socially and educationally. Opinions in reply have been received from 24 States, including two Provinces of Canada.

Without exception these officials say that the "purely legitimate Agricultural fair pays better financially in the long run; that the "wide-open" fair is not a financial success, that it is offensive to the better class of people on whom the fair must rely for continued support, and is demoralizing to the surrounding community.

They are also unanimous for rigorously excluding all games of chance; for strictly prohibiting all alcoholic liquors, except California; and they severely condemn vulgar rent-shows and suggestive demonstrations on the outside of tents.

As to whether "circus" features tend to absorb time, strength and interest of patrons to any disadvantage to the exhibitions of farm, home, school and factory products, the majority believe that they do, and therefore should not be encouraged. One-half of the writers lean to the view that entertainments, those foreign to the real features of the fair, should be done away with as fast as the people can be educated to appreciate the fair for its own sake.

THE CIVIC COMMITTEE.

Boston, Mass., Aug. 1.

Very Dry in Idaho.

It is very dry here now, but the bees are doing some great work on catnip, buckwheat, and mugwort. I have nice, strong colonies from two colonies I purchased a year ago. I try to prevent swarming as far as practical. I use 8-frame hives, but the best helper I have is the American Bee Journal.

J. C. LARKREE.

Good Season for Honey.

I am a beginner in the bee-business, and hope, in time to make a success of it. I worked for increase this year, so I do not expect to get much honey, although this has been a great season for honey here. There is an abundance of sweet clover, which the bees are working on. I hope and expect soon to be a member of the National Bee-Keepers' Association, as I think it is a worthy cause.

Building a Mouse-Proof Honey-House.

G. M. Doolittle tells how to build a honey-house, on page 436, emphasizing the necessity of having it "mouse-proof." I think I can tell the readers of the American Bee Journal how to erect such a building and have it mouse-proof without the trouble and expense of "lining it with tin," and I can do it best by telling how I built my own.

After laying the sills on good-sized rocks, three feet apart, and placing the joists on top of the sills, I then laid the floor, good, matched material, free from knots, and flush with the outside of the joists all around; then spiked 2x4 scantling flatwise on top of the floor clear around the outside, like a plate; then nailed the studding to this; sided it with good, matched drop-siding, painting the tongues with thick paint as fast as it was put on.

The building is provided with live windows and a door, all provided with screens, the latter self-closing, and which I leave on summer and winter, so that if the door is care-

Bee-Keeper's Guide

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

BEES WAX

27A15 We will pay 20¢ cash, per lb. for pure, bright yellow beeswax, and 20¢ cash, per lb. for pure, dark beeswax delivered here. CHAMBERLAIN MEDICINE CO., Des Moines, Iowa. Please mention the Bee Journal.

FOR SALE

35 acres, well fruited to cherries, peaches, plums, pears, apples, currants, raspberries, blackberries, and strawberries. Good house, barn, vegetable green-house, honey-house, 50 or 100 colonies of bees, situated in good bee-locality. Title clear. For particulars address:
31D3R A. L. KILDOW, Sheffield, Ill.

Farm Wagon Economy.

The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., who make this Electric Handy Wagon and the new famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

ELECTRIC

This wagon is composed of the best material throughout—white hickory axles, steel wheels, steel bounds, etc. Guaranteed to carry 400 lbs. These Electric Steel Wheels are made to fit any wagon, and make practically a new wagon out of the old one. They can be had in any height desired and any width of tire up to 8 inches. With an extra set of these wheels a farmer can interchange them with his regular wheels and have a high or low-down wagon at will. Write for catalog of the full "Electric Line" to Electric Wheel Co., Box 10, Quincy, Ill.

lessly left open the screen will close, keeping out mice, cats, or anything of this kind.

The building has been in use three years, and I can say, truthfully, that not a single mouse has ever been inside of it. My house was built in the same way, except that between the joists is filled with grouting level with the top, with a double floor. In the six years that we have occupied it, not a mouse has found its way into any part of it—upstairs, down-stairs, or between the walls.

Another advantage is claimed for a house built in this way, that is, in case a tornado twists the building into kindling-wood, the floor will be left, so that if the family take refuge in the cellar they will be safe; but I am very glad to be able to say that we have not yet been compelled to test the truth of the statement.

Mitchell Co., Iowa.

A. F. FOOTE.

Good White Clover Flow.

I have 25 good colonies, have taken off 922 pounds of fine white clover honey, and have about 100 pounds more to take off. We have had a fine flow. Bees are in fine condition. I have not lost a swarm this summer. Several colonies swarmed four times apiece. I put them back and cut out the queen-cells. Honey sells readily at 12½ cents per section. I have 500 pounds yet in cases put away for sale. My brother, D. D. Cole, has taken off 255 pounds—very fine honey.

J. W. R. COLE.

Audubon Co., Iowa, July 23.

No Honey-Flow.

I have been interested in bees for some time. Two summers ago I bought a colony with a tested Italian queen; last year my increase was a prime swarm and an after-swarm, which wintered well. Two of them cast two swarms each this year. Last year I had a surplus of 40 pounds of honey, but as yet I have no surplus, as there has been no honey-flow in this section. I want to try feeding.

CAS. HARDIN.

Greene Co., Tenn., July 22.

Treatment for Bees Supposed to be Diseased.

On pages 487 and 488, I notice that a bee-keeper in Massachusetts has trouble with his bees, which seems to be a disease, or some consider it so. Thus far I consider the trouble arises, first, from a lack of vitality in the queen; second, chilling of the brood; and third (and principally), starvation in its various stages. Care should be taken to keep bees dry and warm in the spring, or the whole season; plenty of good food supplied when they are short in honey, and a good watering-place in the apiary kept going from early spring until quite late in the fall. New blood should be introduced, and to make sure work of it, when bees are bad, they might be put on full sheets of foundation. This followed carefully will make a great improvement, and should rid the bees of dying brood. Many have this same thing in their yards in a degree, and do not notice it until it becomes quite bad. Then the case becomes serious; the bees will amount to nothing.

D. J. BLOCHER.

Stephenson Co., Ill., Aug. 8.

The Mulberry as a Honey-Plant.

Do you believe in telepathy? Then how do you explain the fact that since I accidentally discovered the value of the white mulberry as bee-food for honey-producing—before the article in reference to mulberries had appeared in the American Bee Journal (page 493)—enquiries have been received, special explanations being desired?

If the editor will permit me space I will cheerfully add the result of recent and more extended experiments. I should have been more explicit in some of my details in the first article, to which I will advert in this. I am not certain as to how large dimensions the white mulberry tree attains. The black, I know, grows to be large, in some sections yet for saw-logs, but the white may not

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal!

one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on a steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding Round-Edge Tools. the holes in the standard are used instead of the notches.

GEORGE W. YORK & CO., 114 & 116 Erie St. Chicago, Ill.

grow so big, but large enough to produce abundant shade and bear quantities of luscious fruit.

The berries begin to ripen about the first to the second week in June, and continue to ripen until nearly the last of July—according to the season. If cool and wet, the berries do not mature so quickly. But the greatest advantage is that the fruit ripens gradually, affording extended feeding time, so unlike other netting-producing fruits, of few days' duration. The simplicity with which the berries can be utilized—easily gathered and crushed—that a small child can readily be taught to feed it to the bees.

The fact that the bees take kindly to this new product is beyond question—they simply devour every vestige that can be made available, leaving only the seeds.

Now as to the kind of honey produced. I opened up a hive the other day and found both comb and honey which I have good reason to believe was the result of the mulberry harvest. The comb was new, beautifully white, and especially translucent; the honey was as pure and white as any sweet clover honey, and the flavor much like that of alfalfa, but innocent of the slightest "foxy" taste of the basswood and pungent blossoms, not to mention buckwheat. I can imagine no more delicate flavor, and in appearance it is ideal.

Of course, the natural argument will arise: "How do you know it wasn't white clover honey?" Well, I'll have to resort to woman's final reason—"Cause." I may as well attempt to explain the sound of a violin—you can only know by hearing it; the honey you can only appreciate by tasting.

You can, by no possibility, miss doing a good thing in planting white mulberries in every available place around your home. Stick cuttings in the ground and let them grow.

To the good wife let me say, that white mulberries stewed with about one-fourth currants—or pie-plant—makes one of the most delicious jellies or jams in the world. No sugar needed.

Cook Co., Ill.

Dr. PERRO.

As to Editors of Bee-Journals.

It seems to some a matter of reproach that editors of bee-journals are not completely informed on all topics nearly or remotely connected with the subject of beekeeping. Arthur C. Miller complains of the silence of the text-books and the ignorance of editors as to the laws of heredity and the principles of breeding; and now F. L. Thompson, in the Progressive Bee-keeper, takes up the refrain at still greater length. This reproach against the ignorance of bee-editors does not seem to be bitterly resented by at least one editor, for the editor of the Progressive makes no word of reply, and it is not likely that any other will attempt to deny the charge. No one is more likely than the editor of a bee-journal himself to be conscious of his need of information; and the reproach that he has not yet learned all that is to be known about beekeeping is likely to strike him much as would the reproach that he has not strength to live on without eating.

The mistake that Mr. Thompson seems to make is in supposing that editors of bee-journals pose as the repositories of all knowledge on the subject of beekeeping. If bee-keepers had any such view, then their journals would be made up entirely of editorials. But at the present day no bee-journal is conducted on any such line. Instead of being filled up entirely with what the editor has to say, the bee-journal of the present day seeks contributions from all quarters. If any bee-keeper has had sweet opportunity for becoming particularly well informed on some one sub-

To make only pay, use Sharples Cream Separators. Book "Business Dairying" & Cat. 212 free. W. Chester, Pa.

ject connected with bee-keeping, contributions from him upon that subject will be eagerly sought. Instead of a bee-journal being a mouth-piece through which one man seated on a pinnacle may deal out wisdom to the common herd below, it is, rather, a clearing-house through which may pass in exchange the gathered wisdom of all.

Still greater is the mistake that a bee-journal should seek to represent knowledge upon a subject with which the editor is not entirely familiar. Having learned that an article having some reference to the matter of scientific queen-rearing had been sent to appear in the columns of this journal, Mr. Thompson says: "I fear that either it will never get there, or, if it does, it will be accompanied by a crushing footnote, written more in sorrow than in anger." If he will turn to page 382, he will find the article in question, with a footnote not at all "crushing," containing neither sorrow nor anger. So far from that, he will be rejoiced to find the footnote only commendatory, saying, "Bee-keepers have much to learn from the tendency of other lines upon it, and his joy will be increased to find that sufficient progress has been made to commend heartily in-breeding on the lines indicated."

No, the bee-journal that seeks to represent knowledge that may benefit bee-keepers in general would be committing suicide. The watchword with all should be, and probably is, "Let there be light."—cleanings in Bee-Culture.

Red Clover—How Important is It?

The desire to obtain the nectar secreted by red clover is one of long standing; and the common impression is that a very large quantity of nectar per acre would be secured from it if the flower-tubes were not too deep for the reach of the honey-bee. Latterly some discredit has been cast upon red clover as a honey-plant, even supposing that all its nectar could be secured, by the fact that it is not a plant of universal cultivation.

There are a few plants that yield an enormous amount of nectar; but they are kept only in greenhouses, averaging less than one plant to the acre, they are valueless from a bee-keeper's standpoint. If, however, any good honey-yielder were widely distributed in dense quantity over a single State, then it would assume some degree of importance. The buckwheat crop of the State of New York would be no triding matter, even if not another acre of buckwheat were found elsewhere in the United States. If it were possible to obtain certain bees that would double the buckwheat honey crop of New York, the amount of money gained by that would warrant no small outlay. Is it not possible that there are single States in which the nectar secreted by red clover would amount to several thousand dollars?

But is red clover confined to a rather limited area? It would be interesting to know just what is the average acreage. Lacking that, some estimate may be made from the amount of clover seed raised. The government statistics give us the figures, and it is probably safe to infer that by "clover seed" is meant that from red clover. According to the last census available, that of 1900, an amount of clover seed, large or small, is given as being raised in every State and Territory of the United States except Montana and Wyoming. It certainly shows that it is not confined to so small an area as some suppose.

The North Central division lends with a product of 2,544,864 bushels. The South Central comes next with 77,783 bushels; the North Atlantic, 71,128 bushels; South Atlantic, 35,155 bushels; Western, 24,250. Total, 3,733,180 bushels.

This shows a very unequal distribution; but this distribution of the growing plants is by no means what the figures would indicate. From the States that are the greatest producers, as New York and Pennsylvania, large quantities are exported, and, of course, other States import, thus making the average grown in the different States much more uniform than the amount of seed produced.

If all the seed raised is sown again, and it is not likely that it is ever used for any other purpose, and if a peck of seed is sown to the acre, it would cover a little more than 11,000,000 of acres. To speculate as to the amount

A Superior Red Clover Queen

(AN UNTESTED ITALIAN)

For sending us One New Subscriber and 25 cents (\$1.25 in all.)

We arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us this season. This bees average quite a good deal the longest tongues of any yet measured. The breeder he uses is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

We would like each of our present readers to have one or more of these fine Queens. Simply send us the name and address of a new subscriber for the American Bee Journal for one year, and 25 cents extra, and the Queen will be mailed to you. Our queen-rearers is now caught up with orders, and expects to be able to mail them hereafter within 48 hours after we receive the order. He is in another State, and we will send him the Queen orders as fast as we get them at this office. He is prepared to rear and mail a large number.

The cash prices of these Queens are \$1.00 each; 3 for \$2.70; or 6 for \$5.00. Send all orders to

of honey that could be obtained from this acreage would be outside of the present inquiry, and it is doubtful as to there being sufficient data to justify anything like a reasonable estimate. It is only desired to show that the aggregate of red clover territory is no trifling affair, and that it is widely distributed.—Gleanings in Bee-Culture.

Distance of Apiaries.

At a conference of the Victorian Apianists' Association, as reported in the Australasian Bee-Keeper, it was adopted as a rule of this Association membership, that in the future establishment of apiaries a distance of at least three miles should be preserved from any existing member's apiary unless by mutual consent, and that failure to observe this rule, should on being properly brought before the executive of the Association, disqualify for membership.

Another rule aided, provided that "any member practicing adulteration of the products of the apiary, or guilty of fraudulent proceedings as a bee-keeper, should be disqualified."

It was pointed out by one and another that the very grave mistake of crowding close to another apiary, often of superior numbers, was made by beginners in the industry because they were ignorant of the severe loss it entailed on themselves, especially; and by others who lacked that moral sense of honor and fair play that even rascals will observe in keeping at a fair distance from their neighbor. Several bee-keepers thought the distance should be five miles apart, and no doubt was expressed that this is in all but the very best of bee-country quite close enough, and that three miles in the off or bad season is very much too close for apiaries of any considerable size.

The Bee in Law.

Under this caption has begun in Gleanings in Bee-Culture a series of articles by F. D. Fisher, with a view to having them afterward in book form for convenient reference. This will serve a convenient purpose, especially as laws of different States are by no means alike. As to ownership, Mr. Fisher says:

With regard to bees, Blackstone, the great lawyer, says: "Bees also are *ferre nature* (wild by nature); but when hived and reclaimed, a man may have a qualified property in them by the law of nature as well as by the civil law."

And to the same purpose, not to say in the same words with the civil law, speaks Bracton: "Occupation, that is, hiving or including them, gives the property in bees; for, though a swarm alights upon my tree, I have no more property in them till I have hived them than I have in the birds which make their nest therein; and, therefore, if another hives them, he shall be their proprietor; but a swarm which flies from out of my hive is mine so long as I can keep it in sight and have power to pursue them; and in these circumstances no one else is entitled to take them."

But in respect to such animals as are in the habit of going and returning, as pigeons and bees, which are accustomed to go into the woods and fields, and come again, we have this traditional rule that, if they cease to have the intention of returning, they also cease to be ours, and hence the property of the first taker, because they cease to be what are termed *animus revertendi* when they have discontinued their habits of returning.

Ownership in bees is *ratione soli*; that is, bearing reference to the soil, and is said to be the ground of ownership in bees. So in the civil law, if a swarm of bees had flown from A's hive they were reputed his so long as they remained in sight and might easily be pursued; but if they did not become private property until they are actually hived. Bees, along with other wild animals, furnish the only distinct class of chattels which have been made the subject of primary occupancy. Even here, notwithstanding the universal principle of law, that all mankind may pur-

sue and take animals, whether of the air, earth, or water, in a wild state, the first occupant becoming the owner, there is found a restraint which ownership of the soil imposes, and which fastens the closer as population grows and civilization advances.

DO YOU WANT A HIGH GRADE OF

Italian Bees and Queens?

2-frame Nucleus with Untested Queen, \$2.00, purchaser paying express charges.

NOTICE.

Having sold my property I am required to give possession soon, as well as move my entire apiary. Therefore I will quit filling orders Sept. 1. Our bees will be put in a more roomy place, and there prepared for winter.

Months.....	July and August.		
Number of Queens.....	1	6	12

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Aug. 3.—For choice white comb honey the demand is equal to the receipts at 15c per pound, but off grades are slow at 1 to 3 cents less. Extracted is selling more freely at 10c a case for white; amber, 5c 5/8c. Beeswax steady at 30c. R. A. BURNETT & CO.

CINCINNATI, May 17.—No demand for comb honey, also stock of it well exhausted. Extracted very dull; sales are more or less forced; lower prices from 1/2 to 1 cent per pound. C. H. W. WEBER.

BOSTON, Aug. 3.—The honey market is practically nominal, demands being nothing owing to the warm weather. We have had a lot of new honey in that sold at 17c. Extracted, light amber, 8c; amber, 6 1/2c.

BLAKE, SCOTT & LEE.

OMAHA, Aug. 8.—New comb honey is arriving by express in small quantities from Iowa and Colorado, and selling at \$3.50 per case in a retail way. California extracted honey is being offered carlots at 45¢/46¢/c per pound, l.o.b. California shipping-points, but we have not heard of any sales having been made thus far. The production of extracted honey seems to be quite large this year in Colorado, Utah and California. PEYCKE BROS.

NEW YORK, Aug. 7.—There is some demand for new crop of comb honey, and receipts are quite numerous for this time of the year. They have been principally from the South, but we are now beginning to receive a few from New York State and nearby. We quote: white, 15c; No. 1 white, 13¢/14¢; amber, 11¢/12¢. No new buckwheat is on the market as yet, and we do not expect any before next month.

Extracted is decidedly dull. Plenty offerings, with only a limited demand, and quotations are rather nominal. We are selling at from 5¢/5 1/2c, according to quality, and Southern in barrels at from 4¢/4 1/2c to 5¢/5 1/2c. Beeswax, 26¢; and declining; for the present we quote 27¢/28¢. HILDRETH & SEIGLEIN.

ALBANY, N. Y., June 18.—Honey market is dull with no receipts or stocks and little demand. It is between seasons now. Prospect of good crop in this vicinity from what bees there are left, the greater portion having been killed by foul brood exterminators. H. R. WRIGHT.

DES MOINES, Aug. 7.—There is very little doing here in new crop of honey. Some small lots of near-by produced comb honey are on the market and selling in a retail way at \$3.50 to \$3.75 per case. We do not look for much trade in this line before Sept. 1. Our market does not consume a great deal of extracted honey. PEYCKE BROS. & CHANEY.

DETROIT, July 18.—Fancy white, 15c; No. 1, 13¢/14¢; no dark to quote. Extracted, white, 6¢/6 1/2c; dark and amber, 5¢/5 1/2c. BEESWAX, 26c. M. H. HUNT & SON.

BUFFALO, Aug. 8.—Fancy new 1 pound comb honey, 16¢/17c; darker, proportionally lower, from 15c down. Old not wanted and neglected. Beeswax, 22¢/28c. BATTERSON & CO.

KANSAS CITY, June 14.—Very little honey on our market, but what is damaged by being granulated. Sales are light at 15 cents for best grade No. 1 Colorado. Amber, 13c. Beeswax firm at 25¢/26c.

W. R. CROMWELL PRODUCE CO., Successors to C. C. Clemens & Co.

SAN FRANCISCO, July 31.—White comb, 11¢/12c; amber, 9¢/10c; dark, 6¢/7c. Extracted, light amber, 11¢/12c; dark, 10¢/11c; amber, 4¢/4 1/2c. Beeswax, 26¢/28c.

Only very moderate quantities offering and nothing in spot supplies to indicate that this year's yield was of liberal proportions. Much of this season's honey, however, is being held back at producing points. Bids of large operators continue under the views of holders.

KANSAS CITY, Aug. 6.—Some very fine Missouri honey is now on the market, selling at 16¢/17c per pound for fancy white comb. Colorado and Utah shippers are offering new comb honey in carlots for first half of August shipment at 16¢ per pound for No. 1, and 15¢/16c for No. 2, l.o.b. shipping-point. The market for extracted honey is as yet rather unsettled, with prices ranging from 45¢/46¢ c, l.o.b. shipping-point. Buyers, however, seem to be in no hurry to make contracts. PEYCKE BROS.

We have a Large Stock on hand and can ship promptly.

SEND US YOUR ORDERS FOR

Hives, Extractors

OR ANYTHING YOU WANT IN THE BEE-KEEPING LINE.

WE MAKE ONLY THE BEST.

More Bee-Keepers' Paradises....

E. R. Root has just returned from a 6,000-mile trip through some of the best bee-locations in the world, and has already begun his series of write-ups, accompanied with fine photos, in Gleanings in Bee-Culture. The following editorial appears Aug. 1, and will give something of an idea of what he will describe:

Some little time ago I promised to tell about the bee-keepers' paradise in Texas. I have this on the docket, and it will appear as I take up the line of my travels. But since running across that paradise I have run into two or three others. There is one west of the Rockies, in Colorado, that is not yet overstocked with bees or bee-keepers; another one in Central Idaho—in fact, I do not know but the whole State. These will be described in turn. The fact is, millions of capital are being invested in irrigation; irrigation means alfalfa; alfalfa means a paradise for bees. But I found all along my trip that alfalfa-growing preceded bee-keeping by two or three years, for it seems to take about that length of time before bee-keepers find these gold-mines that have been hitherto unoccupied.

If you are dissatisfied with your present location, and for financial reasons, or on account of health, will be compelled to leave, subscribe for Gleanings in Bee-Culture, and learn something about the great South and the great West. There are many locations in the West that are not yet occupied—splendid bee-locations. If you wish to learn about them, send 25 cents for a six-months' trial subscription, or \$1.00 for one year and one untested Italian queen. Or, send \$2.00 and we will send Gleanings one year and one of our celebrated Red Clover Queens.

MEMBERSHIP DUES, \$1.00 a year.

☞ If more convenient, Dues may be sent to the office of the American Bee Journal, when they will be forwarded to Mr. Secor, who will mail individual receipts.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

CLOSED SATURDAY AFTERNOONS.—It seems that some of our customers have forgotten that our office and store are closed Saturday afternoons from July 1 to Oct. 1.

MR. E. M. HUNT, son of M. H. HUNT, of Wayne Co., Mich., was married to Miss Jessica Sawtell, Tuesday, Aug. 13. Heartiest congratulations to them.

ON TO THE THOUSAND.—Still they come—those who are helping to make up the first 1000 members of the National Bee-Keepers' Association. These names have come to this office, [with the dollar each, since our last issue:

GEORGE W. HARRISON, JOHN CONSER,
H. P. HENNINGSEN, FRANK L. GOSS,
THOS. J. WOODWARD.

MR. H. W. CONGDON, of Hardin Co., Iowa, called on us Aug. 9. He was on his way to Buffalo, to visit the Pan-American Exposition, and also his parents who live near there. Mr. Congdon has between 40 and 50 colonies of bees, and hopes next year to establish out-apiaries. His crop this year, owing to the drought, has not been very much. Still he is not discouraged.

DR. WILLIAM CRENSHAW, of Fulton Co., Ga., dropped in to see us Friday, Aug. 2, when on his way home from the national meeting of the dentists of America, at Milwaukee. Dr. Crenshaw has about a dozen colonies of bees, and is doing nicely with them. Of course, he keeps them more as a pleasurable pastime, in connection with his profession, rather than as a source of financial profit. The Doctor is a very pleasant gentleman to meet. Success to him.

MR. N. E. FRANCE, of Grant Co., Wis., inspector of apiaries for that State, will be the judge of the apianian exhibits both at the State Fair in Milwaukee, Sept. 9 to 12, and at the Fair at Platteville, Sept. 17 to 20. The judging will be well done, and all will be satisfied.

Mr. France says he has been quite busy treating foul brood, and has had many obstacles to overcome the past year. But he says further that he has now gotten the disease pretty well stamped out of the State, and all remaining cases under quarantine control.

Oh, that every State had a bee-inspector, and every one equal to this one with a French name!

PAN-AMERICAN BUILDINGS.—On the preceding page we show two of the many beautiful buildings of the Pan-American Exposition.

The Agricultural Building contains exhibits of agricultural products, processes and articles pertaining to the farm, of a most interesting character. In these days of scientific farming the successful agriculturist finds it necessary to acquire a fair knowledge of many of the sciences. The agricultural exhibits show

many of the wonderful possibilities in farm work.

At the Pan-American Exposition, we understand, are shown the largest display of electrical machinery and appliances ever presented. Nearly every article is the very latest design, and the visitor will find novelties without number in this interesting division. The Electricity Building is of very rich and beautiful design, having a broad loggia on the southern side, while the roof-line is broken with domed towers.

Doubtless many of our readers will have an opportunity to see the Exposition while attending the annual meeting of the National Bee-Keepers' Association at Buffalo, next month—Sept. 10, 11 and 12.

HE WORKS STANDS.—In one of the recent issues of a certain bee-keeper an old and experienced writer says, "I work 200 stands." Just think of working the "stands!" Wonder what he does with them? But quite likely he meant colonies instead of stands. It's almost beyond understanding how some bee-keepers stand around and still talk about their stands of bees. Or, perhaps they'll say they had so many hives in the spring, and increased to twice as many "hives." They don't say whether they bought the extra hives from some bee-supply dealer, or got them by "in-breeding!"

Of course they mean colonies, and not "stands" or "hives."

A BADGE PIN for the members of the National Bee-Keepers' Association is thus suggested by Mr. N. E. France:

"I wish the National Bee-Keepers' Association would adopt some design for a badge pin, and every member have one to wear. The one used at Chicago is good enough. I could relate several instances where persons have asked what that bee-keeper's badge represented. (I wear one all the time.) I answer always, 'National Bee-Keepers' Association.' In one case I was called to settle a dispute about bees, and was introduced as State Inspector and member of the National Bee-Keepers' Association. The fact that I belonged to said Association seemed to settle all dispute, and both were willing to leave their troubles for my settlement. Neither of them belonged to the State or National organization of bee-keepers, but they will join them both at our next meeting."

Hurrah for a badge pin for the members of the National Bee-Keepers' Association! Why not adopt one at the Buffalo meeting? True, the badge pin used at the Chicago convention last year is all right. Why not adopt it?

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

	5lb	10lb	25lb	50lb
Sweet Clover (white).....	\$.70	\$ 1.20	\$ 2.75	\$ 5.00
Sweet Clover (yellow).....	1.00	1.80	4.25	8.00
Alsike Clover.....	.90	1.70	3.75	7.00
White Clover.....	1.00	1.90	4.50	8.50
Alfalfa Clover.....	.80	1.40	3.25	6.00

Prices subject to market changes.

Single pound 5 cents more than the 5-pound rate, and 10 cents extra for postage and sack. Add 1 cent to your order, for cartage, if wanted by freight, or 10 cents per pound if wanted by mail.

* Editorial. *

Beware of Honey-Dealing Frauds!

Such caution, not many years ago, was absolutely necessary. It was our privilege, as well as enthusiastic pleasure, to help drive out of business a few of the most daring honey-sharks that ever "sharked." And so far as we know they are not "sharking" bee-keepers now, we are glad to say. Many of our readers have at least pecuniary reasons for remembering the Horrie-Wheaton-McConkey crowd that a few years ago so successfully fleeced the unsuspecting honey-producers, here in Chicago. Just now we are not aware of any here that are getting ready to "do up" the "easy" bee-keeper. And yet it is always well to be on one's guard, for no one knows just when the wolf will show his claws through his sheepish covering.

It is a pretty good rule to make a thorough investigation before shipping honey—or anything else, for that matter—to new firms or strangers. The facilities are fairly ample in these days, to learn of the financial responsibility and character of those who solicit the products of the apary and farm. Also, it is generally true that an old and established firm can do as well, if not better, with any produce entrusted to them, than can new firms. At any rate, we should hesitate a long time before changing from "the old and tried" to the new and untried. The latter may be all right, of course; and then, again, they may not. But if you must experiment with new dealers, our advice is to ship no more at a time than you can afford to lose—until you are satisfied they are honorable and satisfactory in their business conduct.

We can assure you that it isn't pleasant to feel the necessity of giving such caution as the foregoing, as it may be an injustice to some splendid new firms; and yet, the good and well-meaning must sometimes suffer on account of the fraudulent actions of those for whom they are not in any way responsible. But such is the stern law of public trade and dealing. It is hard, and yet there seems to be no other safe way of escape.

Seasonable Articles, that is, articles given at the right time for putting into practice the suggestions contained in them, have been strongly urged at times. What is the use of giving advice about a thing just as the time of year has ended when that advice can be put into practice, and nearly a year must intervene before the next opportunity to try

it? In spite of that, F. L. Thompson advocates in the Progressive Bee-Keeper that the close of the swarming season is the best time to discuss the swarming problem. And he gives reasons for it that are not to be despised. Right when a thing is yet fresh in mind with all its particulars is a better time to give it than to wait till particulars are partly forgotten, and enthusiasm has died away. One trouble is, that if a year is allowed to elapse, in many cases, if not in most cases, the bee-keeper concludes he will not write at all.

A horticulturist once gave as a rule for the best time to prune trees, "Prune when your knife is sharp." It may be a good thing for the readers of this journal to follow something like the same rule.

Whenever you have any item that you think would benefit some other bee-keeper, sit right down and write it off, in season or out of season. Sometimes some little thing will be learned, and just because it is a little thing it is not thought worth while to send it. Bee-keeping is largely made up of little things, and many a beginner strikes upon a little thing that some of the veterans have not yet learned, and will be glad to know.

When you have gained some new light, send it in. If it is something that is so generally known that it is not worth while to print it, you need not feel hurt that it does not appear in print. But the danger of that is small. A good many things bear repeating.

Don't be afraid to add your mite.

A Novel Method of Feeding Back to get unfinished sections completed is thus given in the Bee-Keepers' Review by Fred H. Fargo:

The honey to be fed back, which may consist of unfinished sections, or any combs of suitable honey from three to four pounds in quantity, is daily placed in a hive (the entrance to which must be contracted to admit only one or two bees at a time) a few rods from the apary, and not a great distance from the colony upon which are placed the unfinished sections to be completed. A section of honey, bruised so that the honey is ready to run, and covered with bees, is then taken from the colony upon which are the unfinished sections, and placed in the hive containing the honey to be fed. Or, we can place a section or piece of comb honey on the alighting-board and leave it there until sufficient bees from this colony are taking the honey, then place in the hive as above stated.

These bees, thus carried from their home and placed in a hive containing honey, will work back and forth between this hive and their home, carrying the honey to the latter, and the strange part of it is that they will defend both hives from robbers.

In selecting the colony to do this work, choose one containing good workers that will protect their own home against the intruding robber-bees. The fact that the work of carry-

ing away the honey is commenced by bees that are *all from one colony* accounts for their combining in a defense of the spoil.

Commenting upon this, Editor Hutchinson says:

"If one had broken pieces of comb honey, that method might be all right; but for the feeding of extracted honey I think that I should prefer a regular feeder that could be set upon the top of the hive in which the work is being done."

It is barely possible, however, that in some cases there would be an advantage in Mr. Fargo's plan, even when feeding extracted honey. May there not be an advantage in the fact that the bees are getting something from *outside the hive*? Some have complained that after a time the bees showed some weariness about working on feed in the hive, although it is possible this was only when feeding on sugar syrup.

There is one view of the case in which Mr. Fargo's plan might be an advantage, even if most of the feeding were done in the usual way. It is probably always the case that when there are sections to be finished, there are at the same time sections that contain only a small amount of honey, that amount being so small that instead of trying to get them finished by feeding back it is better to have them emptied out by the bees so as to be used as baits the next season. If it is true that in all cases the bees will defend the robbed pile as Mr. Fargo says (there seems some reason to believe it when it is remembered that there is often severe fighting among robbers), then two birds may be killed with one stone. When the light sections are put in a pile to be emptied out for baits, as is the practice of many, instead of letting all the bees of the apary work upon them, just take Mr. Fargo's plan, and let the honey be all used by one colony.

Washing Black Combs.—It is well known that combs become black with age, especially those in which brood is reared, but it is not so generally known that when such combs are filled with water and allowed to stand a few days the water becomes inkly black. It is reasonable to suppose that when so much of the dark color is soaked out by water, at least some of it will be absorbed by honey, hence it has been the practice for some time, when a choice article of white extracted honey was wanted for show purposes, to use only new combs for extracting. It is suggested in *Gleanings in Bee-Culture* that the same end may be reached by washing the coloring-matter out of the old combs. "Lay the combs flat, fill the cells with water from the nose of a watering-can, then after soaking throw the water out with an extractor."

Contributed Articles.

Making Swarms—How It is Done.

BY DR. E. GALLUP.

ON page 478, is an extract on "Close Imitation of Natural Swarming," by G. M. Doolittle. A Langstroth-Simplicity hive makes a very convenient box with the entrance closed, and a board nailed on the bottom, for a clustering-box. You can set up the box open side outward, as he says, and shake the bees from the combs directly into the box, instead of waiting for them to run in, as in hiving. They will begin to cluster at the top end of the box at once. If you have two or more swarms come out at one time and cluster together, or you have after or second swarms with more queens than one, and you wish to separate them, shake them into the clustering-box and let them stay for half or three-quarters of an hour, and the bees will ball the surplus queens, and roll down to the lower edge of the box, and you can cage them and then measure out the bees with a tin dipper, pour them down in front of the hives, and let them run in, the same as hiving a natural swarm.

I once caged eight virgin queens from one after-swarm, and saved them all. They are naturally reared, and usually good ones. In that case the bees hunt out the surplus queens for you. Sometimes they ball every queen, but not usually. It is an easy matter to tell whether every division you make has a queen, by the actions of the bees. Bees in a clustering-box, or hived on empty frames without a queen, will very soon manifest uneasiness, and begin to run about, etc. But if they have a queen they remain quiet. They will accept any strange queen—even virgins will be accepted, or a queen-cell, or a frame of brood containing eggs and unsealed larvae.

Four years ago I had an observation hive in the wood-house, and the bees were passing out and in through a knot-hole. One of the boys wanted to see bees flying out and in through that knot-hole, so I went to work. I set up my clustering-box in the shade, went to a populous colony, carefully took out a frame of brood and adhering bees, shook the bees into the clustering-box, and as the bees were gathering nectar rapidly there was enough shaken on the bees and in the box to cause them to gorge themselves completely. I placed the comb back in the hive and closed it; I had not disturbed the old colony, either with smoke or drumming, so they went right along with their labor as usual. I went to four different colonies and took the bees from one comb, each in the same manner. I had my smoker on hand in case I needed it, but I did not have to use it. I was careful not to get the queen from any hive. I took a frame of brood from two different hives, inserting an empty frame in their places. It was in the middle of the day, so the old bees were nearly all in the field.

I placed the two combs with the adhering bees in a hive, and hived the cluster, and placed them in the wood-house, and now the boys have the satisfaction of seeing how the loaded bees throw themselves into that knot-hole instead of alighting on the outside and crawling in, as one would naturally suppose they would. The two boys take a great interest in the bees, so I am giving them lessons by actual demonstration.

One can make nuclei for queen-fertilizing or introducing at any time, in the above manner. If there is no unsealed nectar to shake out with the bees, sprinkle them with diluted honey or melted sugar of the right consistency, so they will fill themselves. Be careful not to excite robbers at any time when the bees are not gathering freely. If there is danger, go through the operation just at night. I learned all those kinks of making swarms, nuclei, introducing queens, etc., in old box-hive times, from my old friend Wellhausen, years ago. It takes all the fight out of a bee when gorged with sweet, and shaking them into a clustering-box and letting them stand awhile. They can then be hived and placed where we want them. They are to all intents like a natural swarm. One can take a pint of bees, more or less, from a populous colony, and, for that matter, from a dozen colonies, mix them all up in a clustering-box, and make a good swarm without perceptibly weakening the old colonies, and you get bees of all ages, the same as in natural swarming; and I have always thought that it makes them work with an extra vim.

I have occasionally received a queen from some friend, and have no colony that I wanted to introduce her to. So I would make a swarm for her from several different colonies. As soon as the bees manifest their queenlessness, hive them and let the queen run in with them, and the job is done.

In introducing a virgin, hive them on empty frames, and let them stand for a few hours, say over night, before giving them a frame of brood and honey. For I always like to "set them up in housekeeping," as sometimes they are not satisfied and will start queen-cells if given eggs and larva at once. When we have a swarm, sometimes the weather turns bad for a few days, and then they need honey in the hive, or ought to be fed.

I have moved my bees at times from one position to another by shaking and brushing them from their combs into a clustering-box, moved the hive to the new stand, and then after letting them stand awhile run them into the hive, and they are moved.

Orange Co., Calif.

Italianizing Colonies of Black Bees.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes that: "I am a beginner in bee-keeping and wish to know how I can best manage to Italianize ten or twelve colonies of black bees, with the view of being least liable to go wrong. I am taking the American Bee Journal and am so captivated with it that I read each number over and over before I file it away for binding. And so I should like to have you answer through that paper, and then I shall have your answer where it will not get lost."

Well, your last thought is one not often hinted at, and I must confess it is a good one, where bee-papers are properly filed away for future reference. I have mine so filed, and there are few things in the back volumes of these papers, which are of practical value to the apiarist, but what I can turn to them in a very short time. If more of our bee-keepers realized the value of the back numbers of the bee-paper they are taking, there would be more wisdom in our ranks than is often manifested, and less bee-papers found among the bundles the "paper-rags-buyer" carries off after visiting their homes.

But to the question: The Italianizing of your apiary depends upon whether you are desirous of doing all the work yourself, and thus learning all the little kinks of queen-rearing, or whether you simply wish to have all of your bees of the Italian variety as speedily as possible, with no further attention being paid to the matter. If the latter, then I would advise buying untested queens of some reliable dealer; learn through him how to introduce them safely, and when introduced successfully you will have solved the matter.

If, on the other hand, you would like to know something of queen-rearing yourself, (and no bee-keeper is fully a competent bee-keeper until he is perfectly familiar with this part of the work), then buy a queen of two different queen-breeders, each one being good enough to stock an apiary with, and rear queens from one and drones from the other. Keep down all black drones by using only worker-combs in the brood-chambers of the black colonies, except a little piece three or four inches square in one comb, keeping that comb in a certain position in each hive, so that once every three weeks you can take these combs from the hives and shave the heads from the nearly mature drones.

Then if you paint that portion of the top-bar red, right over where the drone-comb is, you can at once tell where this comb is, should the frame get misplaced, from any reason, and if you have this comb near the top-bar to the frame, and keep the frame next to the side of the hive, you will rarely have to decapitate the drones more than twice any season, for it is natural for the bees to store honey at the top of the outside frames, and as soon as honey is stored in the comb, that ends the drones for that year. In this way you will have no black drones, and if your neighbors do not keep bees, and there are no colonies of black bees in the timber in any woods not nearer than four miles of you, you will have little difficulty in having the majority of your queens purely mated, after which your apiary will keep Italian, no matter whether you increase to 1,000 colonies, or allow them to remain at their present number.

But should there be black and hybrid drones in your neighborhood, do not become discouraged, for your young queens would give, practically speaking, pure Italian drones, so that the next year the most of your queens will mate with these, when, by selection after you have seen the progeny, you can soon have the apiary stocked with none but Italians.

By adopting this plan of rearing your own queens you

will get a schooling which, in after life, you would not part with for a considerable amount of money.

No. 11.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

"I BELIEVE, Mr. Bond, I promised yesterday to tell you about robbing in the apiary, when I could get a good opportunity to do so. Well, I've just noticed something about this drone-beheading business that has brought the matter to mind again—I mean those shavings from the drone-comb which I carelessly allowed to fall to the ground at my feet. This is a good time to direct your attention to it, because I believe that fully seven out of every ten instances when robbing breaks out among bees, it is owing to some violation of an important rule—some thoughtless transgression of the law of vigilance, which in an apiary is always in force.

"The sight of those drone-head shavings reminds me of an experience with the worst case of robbing I have ever been compelled to deal with. It was my first experience in api-surgery—the process of drone-decapitation. I went from hive to hive in my search for drones and sliced all the drone-brood I could find. I found it harder work than I had anticipated, and it took more time than I had counted on. And, several other things that proved to be of considerable importance in the course of that experience I failed to see—or foresee, I would better say.

"Well, I was at the sixth hive in the course of my work when, suddenly I thought—but the fact is I had been too eagerly engaged in the work to notice anything else going on around me—I heard a noise like that of a swarm of bees going over my head. For the first time since I had begun the job I looked up—and for about a minute by the clock I kept looking. It took that long for my startled mind to realize what was going on in my little apiary.

"Robbing!" I exclaimed aloud to myself, when I had finally taken in the most prominent signs and symptoms of the case.

"Under ordinary circumstances I would have tried to figure out the cause, or course, of this sudden outbreak, before doing anything else—my mental machinery is built that way—but I had quick wit enough, for the moment, to see that this was no ordinary case of robbing. This was plainly evident to the naked eye, for the air was full of bees, as I had never seen the like before; and they were darting—not merely flying, mind you, Mr. Bond—in every direction, and with a noise which I can't describe, but which sounded in my ears for weeks after.

"It is not usual for me to lose my head on the occasion of an accident, or a sudden, unexpected, frightful occurrence, but on this occasion I was completely 'upset' for—I can't exactly say how long. I noticed, however, that the greater part of the flying bees were near the two hives I had first operated on, so I went there to investigate. On my way I noticed a great many bees crawling around on the ground, and, on looking down to find out the cause, I saw that they were busy on the drone-brood shavings. These, it seemed, contained more or less honey, and as I had carelessly scattered them about each of the six hives treated, they made quite an attractive mess for the bees.

"But that was not all, as I found when I came near the end of the row, for there stood the second of those hives *open*—I had forgotten to replace the cover. This alone is often enough to start robbing in an apiary, but here it was aggravated by a combination of circumstances. These circumstances, however, could not have combined to operate against me had I been thoroughly informed as to certain details. I did not then know that the afternoon would not do as well as the forenoon for such a job of manipulation. Neither did I then know that it was not a good time for such a job when all the colonies are comparatively idle and apparently quiet. And I was also ignorant of the fact that bees are never idle or quiet during the daytime unless there is no honey in the fields.

"The fact is—and I may as well own it, Mr. Bond—I had at that time a slight attack of a complaint known as 'big-head.' Nearly all bee-keepers have had it, more or less severely—usually during a fever caused by unexpected success. I imagined that I had already mastered the intricate science of bee-culture when, in truth, I had many of

the most important things yet to learn. I had made the mistake, too, of supposing that because I had read two or three kinds of bee-books I had nothing more to learn. I have since learned that many essentials in the course of successful bee-keeping can not be found in bee-books—not because those who write bee-literature are not thoroughly informed, but because many things come to our knowledge by experience, and can be learned in no other way.

"Well, I said to myself—I thought out loud during that exciting experience, Mr. Bond—this *is* a sweetness! If only I knew what to do! But I can't think of a blessed thing I ever knew about robbing! And it's getting worse and worse all the time, too! The fracas is on all along the line—and getting worse at the other end, I declare!"

"At this moment I heard some one shouting my name, and on looking around I saw my dear little wife—any possible source of help was *dear* to me just then—standing in the kitchen doorway, gesticulating, and shouting: 'Shut the hives, John! Shut the hives, quick!'

"I didn't at once understand what she meant by 'hives,' not being aware that more than one was open, but I had sense enough to return to me so that I could see the hive right before me and the cover by its side. I had been too completely dumbfounded to see that first important thing to be done toward controlling the robbers! I quickly put that cover on, and then looked to see where my wife had seen another all the way from the house. She pointed toward the end of the line of the six hives. I ran in that direction and slapped the cover on that hive in a jiffy. In the first flush of excitement ensuing my discovery of robbing going on, I had left the hive without replacing the cover, and the robbers had discovered my mistake before I did."

"What did you do next?" queried Mr. Bond. We were walking toward the honey-house as I was talking; and, as I opened the door and asked him to walk in and take a seat, I answered:

"The next thing I did was promptly to execute another suggestion my wife made to me, and partly executed herself when she came running toward the apiary with an armful of quilts and pieces of carpet, calling as she ran, 'Here, John! Take these and throw one over each of the hives not in danger. It will confuse them a little for a while, anyway.' And then she wanted to know whether she hadn't better get her bee-veil and help me get out of the scrape! I tell you, Mr. Bond, it never pays to ignore our women-folks in this business. They remember things better than most of us men, and they nearly always know what to do in sudden and perplexing emergencies."

"Did that put a stop to the robbing?" Mr. Bond inquired, as though not having heard the last sentence.

"Well, no," I replied, "not altogether; though it seemed to bother the robbers for awhile, as my wife suggested it would. But by this time I had recovered my wits, and was now ready for further development. I didn't dare to close, or even to contract very much, the entrance-spaces of the hives, because of the heat in the hives and outside. I had smothered a fine colony in that way the year before, and by the same process also ruined two supers full of nicely finished section-honey.

"Not knowing what I could do further to stop the robbing I got my sprinkling can and for an hour or more kept the hives where the bees were the most aggressive wet all the time. Soon after, night came on; and that put a stop to the business for that day.

"Before I went to bed that night I got out my bee-journals and looked them over for articles on 'robbing.' I found some good things on the subject, and stored them 'for keeps' in my memory. No doubt I had read these articles when the numbers containing them first came to hand, but not having an acute case of robbing on my hands at the time I did not *charge* my memory with the subject-matter, and hence my forgettery took charge of it instead.

"Well, one of the articles on robbing advised the putting of straw or hay in front of the entrance of the hive that was being robbed, and then keeping it wet by sprinkling water on it at frequent intervals. That struck me as a good idea and I determined to try it next day if robbing recommenced.

"Another of the articles said, 'Take the hive that is being robbed and carry it into your cellar, if you have one and it's handy, and leave it there for a few days.' I thought that was a capital scheme, too, and resolved to try it next day, if necessary.

"In another article I found the prescription highly recommended, to change the location of the beleaguered hive, reverse the entrance-front, and cover the hive with a

piece of carpet to disguise it. I am not now certain that this triple-advice was given by the same author, but I am sure that I used it next day in that combination, and with satisfactory results.

"The straw recipe I used next day on those of the hives that were not badly afflicted, and it worked splendidly. I liked it especially because it called for no lifting or carrying of the heavy hive. I have often tried that since, and always with success.

"But the cellar recipe took the cake, of course—that is, as far as effectiveness went. It suited me too, because I wanted to test all these methods, and because I had a cellar; and also because it happens to be handy for emergencies caused by bee-fractions, as you probably remember, Mr. Bond.

(To be continued.)

The People of Rochester, N. Y., vs. The Bees.

On page 483 we published a statement from General Manager Secor concerning the lawsuit between the city of Rochester, N. Y., and Mr. W. R. Taunton, a bee-keeper residing there. The National Bee-Keepers' Association helped defend Mr. Taunton, and of course won as usual.

Mr. Secor has forwarded the following copy of the brief submitted by Attorney Frederick L. Dutcher, counsel for the defendant:

POLICE COURT, CITY OF ROCHESTER, N. Y. :
THE PEOPLE, vs. TAUNTON.

Memorandum for Defendant.

The defendant was arrested upon a warrant based upon an ordinance passed by the Common Council of the City of Rochester on April last, which provides in substance that no bees shall be kept or maintained within the limits of the City of Rochester, *without the permission in writing of the lot owners owning lots within one hundred feet of the hives within which any bees are desired to be kept or maintained.*

At the trial, the defendant moved that the warrant be dismissed and the defendant discharged, upon the grounds:

First.—That the ordinance upon which the warrant is based and which defendant is accused of violating, is *unconstitutional and void.*

Secondly.—That the ordinance in question is not fair, impartial and reasonable, but is *oppressive.*

Thirdly.—That the ordinance in question is an *unlawful attempt on the part of the Common Council to delegate its powers to private individuals.*

Upon this motion, the defendant will not discuss the question whether the Common Council has power to prohibit the keeping of bees, as that question does not arise under this ordinance.

In the first place, the question whether the ordinance is unconstitutional, or whether it violates some other principle of law is a question of law for the Court, and must be decided irrespective of the facts in any particular case.

In *People ex rel. Knicker v. Durston*, 119 N. Y., at page 578, the Court says: "If it can not be made to appear that a law is in conflict with the Constitution, by argument deduced from the language of the law itself or from matters of which a court can take judicial notice, then the act must stand. The testimony of expert or other witnesses is not admissible to show that in carrying out a law enacted by the legislature, some provision of the constitution may possibly be violated."

In the *Matter of Elevated Railroad*, 70 N. Y., at page 327, the Court holds that a Court can not take proof of facts for the purpose of showing a statute valid and regular upon its face to be unconstitutional.

So that the question whether the ordinance is fair, impartial and reasonable must be determined from the ordinance itself.

In *Beach on Public Corporations*, Sec. 512, the learned author says: "It is a well-settled principle that a municipal by-law or ordinance must be reasonable. The Courts will decline to enforce it, it will be declared void as a matter of law."

And again at Section 514, the same author says: "It is, of course, a question of law and not of fact for the Court, and not for the jury, whether any specific ordinance is so unreasonable as to be void."

FIRST.

The ordinance is passed under the so-called police powers of the City, but the police powers of the City are not above the Constitution and are subject to the control of the Courts.

In *Re Jacobs*, 98 N. Y. 98, at page 110, the Court says: "These citations are sufficient to show that the police power is not without limitations, and that in its exercise the legislature must respect the great fundamental rights guaranteed by the Constitution. If this were otherwise, the power of the legislature would be practically without limitation. In the assumed exercise of the police power in the interest of the health, the welfare or the safety of the public, every right of the citizen might be invaded and every constitutional barrier swept away. Under the mere guise of police regulations, personal rights and private property can not be arbitrarily invaded, and the determination of the legislature is not final or conclusive. It matters not that the legislature may, in the title to the act or in its body, declare that it is intended for the improvement of the public health. Such a declaration does not conclude the courts, and they must yet determine the fact declared and enforce the supreme law."

SECOND.

The ordinance is unconstitutional for two reasons. First, it is an attempt to take property without due process of law; and, secondly, the ordinance denies the equal protection of the law, as guaranteed by the fourteenth amendment to the United States Constitution.

In *Stewart v. Palmer*, 74 N. Y. 183, due process of law is defined as follows: "Due process of law is not confined to judicial proceedings, but extends to every case which may deprive a citizen of life, liberty, or property, whether the proceeding be judicial, administrative, or executive in its nature."

In *Re Jacobs*, supra, the facts were that the legislature passed a statute prohibiting the making of cigars in tenement houses in New York and Brooklyn. The Court of Appeals set the statute aside as unconstitutional upon the ground that it was depriving persons of property without due process of law. The Court says, at page 104: "What does this act attempt to do? In form, it makes it a crime for a cigar-maker in New York and Brooklyn, the only cities in the State having a population exceeding 500,000, to carry on a perfectly lawful trade in his own home. Whether he owns the tenement house or has hired a room therein for the purpose of prosecuting his trade, he can not manufacture therein his own tobacco into cigars for his own use or for sale, and he will become a criminal for doing that which is perfectly lawful outside of the two cities named—everywhere else, so far as we are able to learn, in the whole world."

In the case at bar, the ordinance makes it lawful to keep bees in one part of the city, provided certain consents can be given; but to keep the bees in another part of the city would be unlawful if the consents were not obtained.

The Court further says in the case cited, at page 105: "The constitutional guaranty that no person shall be deprived of his property without due process of law, may be violated without the physical taking of property for public or private use. Property may be destroyed, or its value may be annihilated; it is owned and kept for some useful purpose, and it has no value unless it can be used. Its capability for enjoyment and adaptability to some use are essential characteristics and attributes without which property can not be conceived; and, hence, any law which destroys it or its value, or takes away any of its essential attributes, deprives the owner of his property."

In *Butcher's Union Co. v. Crescent City Co.*, 111 U. S. 746, Judge Field says: "The common businesses and callings of life, the ordinary trades and pursuits, which are innocent in themselves, and have been followed in all communities from time immemorial, must, therefore, be free in this country to all alike upon the same terms. The right to pursue them without let or hindrance, except that which is applied to all persons of the same age, sex and condition, is a distinguishing privilege of citizens of the United States, and an essential element of that freedom which they claim as their birth-right." In the same case, Judge Bradley says: "I hold that the liberty of pursuit, the right to follow any of the ordinary callings of life, is one of the privileges of a citizen of the United States, of which he can not be deprived without invading his right to liberty within the meaning of the constitution."

In the case at bar, the ordinance attempts to deprive a person of his property and prevent its use at the mere will of a private individual. The duly constituted authorities of the City do not act in the matter at all, but turn over their powers to private citizens who are taking the liberty at their own sweet will to destroy the property

belonging to another. Can there be any question but that this is taking property without due process of law?

Secondly.—The ordinance is unconstitutional because it denies the equal protection of the law, as guaranteed by the fourteenth amendment of the United States Constitution. Upon this point, we will call the attention of the Court to the case of *Yick Wo v. Hopkins*, 118 U. S. 356. In this case, the Board of Supervisors of the City and County of San Francisco passed an ordinance which provided that it should be unlawful for any person to establish, maintain or carry on a laundry within the corporate limits of the City of San Francisco, without first having obtained the consent of the Board of Supervisors, except the same be located in a building constructed either of brick or stone. It will be noticed that in the San Francisco ordinance the consent of officials was required, while in the ordinance which we are discussing, only the consent of private individuals is required. An ordinance which requires the consent of officials is certainly more reasonable and proper than one which requires the consent of individuals. Public officials are bound not only by the dictates of their consciences, but also by the weight of their judicial oath, and are responsible to the people for their actions; while private individuals can act at their own sweet will. In speaking of this ordinance passed by the Board of Supervisors of San Francisco, the Supreme Court of the United States says, during the progress of its opinion: "We are not able to concur in that interpretation of the power conferred upon the supervisors. There is nothing in the ordinances which points to such a regulation of the business of keeping and conducting laundries. They seem intended to confer, and actually do confer, not a discretion to be exercised upon a consideration of the circumstances of each case, but a naked and arbitrary power to give or withhold consent, not only as to places, but as to persons. The power given to them is not confided to their discretion in the legal sense of that term, but is granted to their mere will. It is purely arbitrary and acknowledges neither guidance nor restraint." And, again: "It does not prescribe a rule and conditions, for the regulation of the use of property for laundry purposes, to which all similarly situated may conform. It allows without restriction the use for such purposes of buildings of brick or stone; but as to wooden buildings constituting nearly all those in previous use, it divides the owners or occupiers into two classes, not having respect to their personal character and qualifications for the business, nor the situation and nature and adaptation of the buildings themselves, but merely by an arbitrary line, on one side of which are those who are permitted to pursue their industry by the mere will and consent of the supervisors, and on the other those from whom that consent is withheld, at their mere will and pleasure. And both classes are alike only in this: that they are tenants at will, under the supervisors, of their means of living." And, again: "For the very idea that one man may be compelled to hold his life, or the means of living, or any material right essential to the enjoyment of life, at the mere will of another, seems to be intolerable in any country where freedom prevails, as being the essence of slavery itself." And, again: "The same principle has been more freely extended to the quasi-legislative acts of inferior municipal bodies in respect to which it is an ancient jurisdiction of judicial tribunals to pronounce upon the reasonableness and consequent validity of their by-laws." And, again: "Though the law itself be fair on its face and impartial in appearance, yet, if it is applied and administered by public authority with an evil eye and an unequal hand, so as practically to make unjust and illegal discriminations between persons in similar circumstances, material to their rights, the denial of equal justice is still within the prohibition of the Constitution." And, again: "The discrimination is therefore illegal, and the public administration which enforces it is a denial of the equal protection of the laws and a violation of the fourteenth amendment of the Constitution. The imprisonment of the petitioners is therefore illegal, and they must be discharged."

No authority is needed except the case cited. A reading of the complete opinion of the Supreme Court of the United States will show that that high judicial authority condemned in the most severe terms ordinances like the one which we are discussing, as being not only not reasonable, but a denial of the equal protection of the law.

THIRD.

The ordinance is void, because it is not fair, impartial and reasonable, and is oppressive.

In *Beach on Public Corporations*, Sec. 90, the author says: "A city, although fully authorized to enact ordinances, can not pass unreasonable ones. The ordinance of a city must be reasonable. It must not be oppressive; it must not be partial or unfair." The same

author says, at Section 512: "It is a well-settled principle that a municipal law or ordinance must be reasonable."

In *Dillon on Municipal Corporations*, Sec. 319, the author says: "In this country, the courts have often affirmed that general incidental power of municipal corporations to make ordinances, but have always declared that ordinances passed in virtue of the implied power, must be reasonable and consonant with the general powers and purposes of the corporation, and not inconsistent with the laws or policy of the state."

In the case of *Yick Wo v. Hopkins*, supra, also held that municipal corporations must be reasonable.

Can it be said that the ordinance which we are discussing is reasonable?

It does not provide that citizens living within one hundred feet must give their permission to keep bees, but that the owners of lots wherever they may live must give such permission. These owners might live in New York, Buffalo, or in Europe, and have no personal interest in the matter, and yet their permission is required. Again, under this ordinance, permission might be obtained, and then, immediately afterwards, the lots within one hundred feet of the place where bees are to be kept might be sold, and permission would have to be obtained of the new owners.

Under this ordinance, a person who owns a lot in the outskirts of the City, a mile from any dwelling, might not be permitted to keep bees, while a person living in a thickly populated district can keep bees, if he get the requisite permission. In other words, under this ordinance, the owner of a lot in the center of a city or adjoining a school-house, may be permitted to keep bees, while a person owning a lot in the outskirts of the City would not be permitted to keep bees. In fact many illustrations might be given, and will readily suggest themselves to the mind of the Court, of the purely arbitrary character of this ordinance and the unjust manner in which it may operate. The private citizen, from mere caprice or ill-temper or bad feeling against the bee-owner may deprive him of the use of his property.

In fact, the right depends wholly upon the personal inclinations and caprice of adjoining lot owners.

FOURTH.

The ordinance in question is an unlawful attempt to delegate the powers conferred by law upon the Common Council to private individuals.

Article Two, Section 12, of the City Charter, provides that the Common Council "has authority to enact ordinances not inconsistent with the Laws of the State, for the government of the City and the management of its business, for the preservation of good order, peace and good health, for the safety and welfare of its inhabitants and the protection and security of their property."

This statute plainly contemplates that the discretion as to whether a certain thing is or is not a nuisance must be vested in the Common Council; but in the ordinance in question, that body has not determined that bees are a nuisance, or that they should only be kept in certain prescribed portions of the City, but the Common Council has turned its powers and its discretions entirely over to private individuals. That the Common Council has not passed upon the question as to whether or not bees shall be kept, is illustrated by the fact that with the requisite permission of adjoining lot owners, bees can be kept in every lot in the City of Rochester. There is an ordinance in force which provides against intoxication in public places; but suppose an ordinance should be passed which would provide that a person might be intoxicated in a public place, provided he could get the written permission of every person owning property within a certain distance of the place where he desired to get drunk—could such an ordinance be supported in the Courts? And yet, such an ordinance would be precisely like the one in question.

In *Birdsall v. Clark*, 73 N. Y. 73, the Court holds that public powers of trusts created by law or charter upon the Common Council or governing body of a municipal corporation, to be exercised by or when and in such manner as it shall judge best, can not be delegated by such body to others.

The ordinance is not a determination by the Common Council that the preservation of good order, peace and health, the safety and welfare of the inhabitants of the city, and the protection and security of their property demands that bees shall not be kept; but the ordinance leaves such questions entirely to the determination of private individuals. Under the ordinance, there is absolutely no restriction to the keeping of bees in any part of the city, providing the bee-owner can obtain the consent of his adjacent lot owners. There can be no ques-

tion but that under the several points made above, the ordinance in question is void and can not be enforced; and it follows that the defendant should be discharged.

JOHN A. BARHITE, of Counsel.
FREDERICK L. DUTCHER,
Attorney for defendant.
Rochester, N. Y.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Late Transferring—Feeding for Winter.

1. Would you advise me to transfer (by the "Heddon short method") those colonies in box-hives to dovetailed, with full sheets of foundation?

2. If I should, and they failed to gather stores enough for the winter, what should be done with them?

NEVADA.

ANSWERS.—1. It will probably be better to wait till next year before transferring.

2. If you transfer upon foundation, and the bees do not gather enough for winter, the only thing is to feed. The danger is that you will feed too late. Better feed in August or early September, then if the bees do gather enough no harm will be done.

Transferring Bees.

I have just transferred a colony of bees as described in the catalog of the A. I. Root Co., and while the bees are working well in the new hive, there seem to be a great many hanging around the old box, going in and coming out, with dead bees and larvae. Is this right? The old box is about 10 feet from the new hive.

MISSISSIPPI.

ANSWER.—As you say you have just transferred, I take it that the second drive has not yet been made, in which case it is all right that the bees left in the old hive should be still at work there. As to their carrying out dead bees and larvae, there may be something wrong and there may not. A few dead bees and larvae do not signify. If many, the danger is that you drummed out too close, not leaving enough bees in the old hive to keep alive the larvae and young bees just ready to emerge. But there is nothing to be done for that now. Ten feet is rather too far to have the old hive from the new one. One or two feet would be better; then when you make the second drive the bees would more readily find the new hive than if their location were ten feet away.

Sowing Sweet Clover Seed.

When is the best time to sow sweet clover for bees, in the fall or spring?

MICHIGAN.

ANSWER.—I don't know. Sweet clover is a contrary sort of thing. It seems to grow with no trouble under the most adverse circumstances (as by the side of a hard road where some effort is made to suppress it), and seems to fall where it has the very best chance. One year I sowed a piece with oats in the spring, the ground having excellent preparation. A fine stand came up, although it did not make a strong growth that summer. The next spring not a plant was left to tell the tale. Every one winter-killed. I think the soft ground was against it, allowing it to heave. Last spring I sowed a few acres with oats, and it never came up; at least not more than two or three plants to the square rod, leaving me \$6.50 out for the trial. I'm inclined to believe that either fall or spring will do; only I think the ground ought to be very solid. From what I have seen, I suspect that the ideal thing would be to sow it in the fall on ground that is not even plowed, allowing cattle or horses to run over it and tramp it in. I don't believe many have made as bad a failure with it as I have, and I wish some one would tell me what was wrong.

Caging the Queen During the Honey Season.

1. If you wish to cage a queen in the honey season, do you cage her in a fine wire cage, or in a cage made of queen-excluder zinc?

2. If you had a queen that you could not use at the time, if you put her in a wire cage, and then in a hive, would the bees feed her? If so, what kind of wire should be used?

3. If you had a young swarm, and only wanted what honey you could get that season, would you cage the queen? If so, in what kind of wire?

SMITH HILL.

ANSWERS.—1. In a wire cage.

2. Generally they would feed her. You could give her a supply of honey or candy, and then she would be independent. Put her in a cage of common wire-cloth about 12 meshes to the inch.

3. I think in most cases I would not cage the queen. It is possible, however, that if the honey harvest lasts not more than three weeks, you would get more surplus by caging the queen in common wire-cloth, or excluder zinc.

Increase from Poor Honey-Gatherers.

I read on page 451 about a colony that gave twice as much surplus honey as the average does; and if an increase was made by swarming, it would be by the poorest surplus gatherers. Do you think that a good colony could not come from the poorer surplus gatherers? I do, for I bought a colony of bees where two small swarms clustered together, which were hived in an eight-frame hive. The colony got a good start last fall, but this spring it was weak, I think, because their queen was old. My bees did well this summer (for I think they have 50 pounds of extracted white clover honey), considering where I have kept them.

MICHIGAN.

ANSWER.—I'm not sure whether I get the drift of your question, but I certainly should not expect as good results, other things being equal, to breed from the queen of a colony of poor gatherers, as to breed from the queen of a colony of good gatherers.

When to Buy Bees in Box-Hives, Etc.

1. If I bought bees in box-hives (the old kind), could I buy early next spring, and transfer to dovetailed hives before swarming-time?

2. What month in the spring would you advise buying?

3. How much sealed honey should be in eight frames to winter one colony? Give about the depth, as I am no judge of pounds in frames, as I am a beginner.

SOUTH CAROLINA.

ANSWERS.—1. Yes.

2. If close by, say less than a mile, better buy before the bees get to flying much. If more than a mile away, then it doesn't matter if you do not buy till time of fruit-bloom. That's safer than to name the month, for months change.

3. Three or four of the outside frames should be pretty well filled with honey, and the others should have honey to a depth of two or three inches.

Hiving Swarms.

1. I noticed in answer to Ben Avon, in Gleanings in Bee-Culture, page 239, about hiving bees on empty combs, he puts four frames in the hive and then fills it with dummies. What are dummies?

2. Do you put on the hives of prime swarms surplus fixtures as soon as they are hived, with a honey-board between the brood and surplus?

TENNESSEE.

ANSWERS.—1. Take a board the size of your brood-frame without top-bar, and nail on it a top-bar, and you have a dummy. I prefer a dummy half an inch shorter than the brood-frame. In thickness it may be anywhere from $\frac{1}{4}$ inch to an inch. If thin, it is better to have a cleat on each end to prevent warping.

2. When working for extracted honey it is advisable to have an excluder over the brood-chamber, in which case the surplus arrangements may be put on at time of hiving. In working for comb honey with full-sized starters in sections,

excluders are not necessary; and when excluders are not used then the surplus arrangements should not be put on the swarm for perhaps two days, so as to allow the queen time enough to become established in the brood-chamber below. If the surplus arrangements are put on at time of hiving there is danger of the queen going above, if no excluder is present.

* The Afterthought. *

The "Old Reliable" seen through New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

CO-OPERATION IN COLORADO.

W. L. Porter's account of co-operation in Colorado, on page 437, seems to show considerable success—a sort of boy-woodchuck success—had to succeed, their local prices being cut down so low, and likely to go lower. Their being driven by their distance from market to act together in selling may eventually have an important effect on honey-selling almost everywhere. The boy who does not *have* to catch woodchuck may also go in to catch one.

WIRE-CLOTH OVER SMOKER-VALVE.

So to keep that bungling "other fellow" from half spoiling your smoker-valve with his bedaubed finger-tips—so simple—just a bit of wire-cloth put over. I'd go to work and thank Harry Howe for that, only no one ever uses my smoker but myself. Page 444.

BEARS AND TURTLE'S EGGS.

We sometimes envy those who have the very best ranges of the world without thinking of the drawbacks. Where the ocean occasionally blows in almost *ala* Galveston, and bears are pretty sure to come in, and both contingencies must be provided against—well, unless a fellow was pretty enterprising he might wish himself somewhere else. Stands seven feet high and bear-fence of barbed wire—say, dear Boss, ask him for a photograph of it.

From Mr. Gifford's saying that sea-turtle's eggs are about as large as hen's-eggs but not as good, I judge they use them—the better article being scarce in howling wildernesses. In a swamp near Fort Wayne, Ind., there used to be enormous turtles whose correspondingly big eggs provoked one to see if they could not be eaten. I have eaten them, but only a pretty hungry man would vote them worth eating. Page 444.

NATURAL INCREASE BY NATURAL SWARMING.

Dr. Miller touches a very sore spot, on page 445. Natural increase by natural swarming has many things in its favor. Perhaps the most important thing (most important if true) is, that the man who undertakes to improve bees, improves them the other way—*disimproves* them—and nature's process will obviate the most of that. But we have to pause before the fact that the best colonies seldom swarm, and therefore we do not get increase from them but from poorer ones.

"DEAR BOSS" OR "DEAR BEESWAX."

And so instead of saying "Dear Boss," shall I say "Dear Beeswax?" Page 450.

THE CROPS OF WAX-SCALES.

If it takes 1,474,560 wax-scales to the pound, and the bee produces six at a crop, the number of crops is 245,760. Conundrum: How many crops will one bee produce as the result of a flow of honey lasting say seven days? I was going to say about three. But that would call for \$1,920 bees. What's the matter? At least three things may be the matter. Possibly the secretions bees add to the scales in making them up into finished wax largely increase the weight. Perhaps it seldom happens that so much as a pound of wax is made during one run of honey. And perhaps my three crops from each bee should be increased. Who knows in how rapid succession crops of scales are raised? Possibly it may be already in print somewhere.

Let's begin again at the other end of the puzzle. A five-pound swarm (22,000 bees) need, in addition to the start their keeper gave them, a pound of wax to fill their chamber. If they really need 245,760 sets of scales, and nearly but not

quite all the bees secrete, that is twelve crops for each bee. So it looks as if when once begun the scale harvests came oftener than once a day. Page 446.

EVILS OF IN-BREEDING.

Anent the Simpson article on in-breeding, I am glad to see in-breeding opposed. Decidedly harmful—and "just awfully" handy. Often the ambitious breeder seems to have only the choice of breeding close, or giving up the thing he is working at. It is in us all to minimize too strongly the evils of a practice which we find very convenient indeed. The wise man should deplore necessary evils, not warp his judgment into praising them.

I can hardly agree that long tongues are merely a symptom. The long pole brings down the persimmons; it is not a symptom of the gale which blows them down. Pages 453-5.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

KINDNESS TO ANIMALS.

I have already, perhaps more than once, referred to thoughtful care and kindness in the treatment of our animal friends. I love the "Beatitudes"—the preface to that grandest, sweetest and best of sermons, "The Sermon on the Mount"—the incomparable 5th chapter of Matthew, with the chapters following. I once heard a superintendent of public instruction of Michigan, say that he would not grant a teacher a certificate who could not repeat the words to "America." Such a one would be incompetent in the line of patriotic instincts.

One is certainly better equipped for all life's struggle who has the "Beatitudes," not only fast locked in memory, but also enshrined in his heart. It is suggestive that of the nine Beatitudes the fifth, or pivotal one (and the one next to "Blessed are the pure in heart; for they shall see God," which is surely best, as it may be said to insure all others) is this: "Blessed are the merciful, for they shall obtain mercy." The dear old Book does not leave us in the dark as to who the merciful man is, or at least as to his character. The merciful man is merciful to his beast. It always makes me grieve to pass a horse whose ribs cry out loudly against his care and treatment. Just think of twenty-eight—a horse has fourteen pairs of ribs—living indictments against one for breaking the 5th Beatitude! What a comfort to drive, to care for, to be with our horses, when they are fat, round, sleek, and beautiful. The added pleasure is enough to urge one to give the care necessary to secure the blessed results. It is real economy thus to feed and care for these faithful servants.

The well-conditioned horse is comfortable, and discomfort preys upon energy and competency. The ribless horse, so far as vision is concerned, is the efficient horse.

Then, too, we ought to give earnest heed to our own reputation. The same blessed Book says: "Avoid the appearance of evil." How sadly must everyone be judged—who drives a lean, hungry, derelict old horse. I can but think that such a one may well pray, "Lord be merciful unto me a sinner." Cruelty to a man, who can speak and defend his right, is indefensible; to a child unable to defend himself, it is despicable. What shall we say, then, of him who neglects or mistreats his horse or cow? These faithful friends can neither defend themselves nor voice their ills. Shakespeare might well have said of such a one, as he did of the miser, "I'd rather be a dog and bay the moon, than such a man." Surely, if we could all realize that our own pleasure, our profit, our reputation, were being weighed in the balance, we would clothe up the uncanny old ribs of the faithful old horse, and would feel more like men, in the assurance that we were not treading under foot that best precept—the golden rule.

All this is written because of an object lesson which our canyon experience brought to us. Each of two men—both splendid men—had their horses with them. These men were both of our party. They are men of high Christian character, and possess, deservedly, the love and sincere respect and esteem of all their neighbors and acquaintances. Yet in one respect there was a contrast. The horses of one were fat, fine and beautiful. Their round, plump bodies, and fine sleek, shining coats, showed that they were subjects of thought-

APIARY OF WM. W. COREY, OF HARTFORD CO., CONN.

ful care and attention. There seemed to be a happy understanding between horses and master. Feeding and watering were always prompt, regular and generous. When out with the saddle, in climbing the steep, rugged mountain trails, a halt and rest was often necessary. If these were at all prolonged, the cinch was loosened. No wonder those horses were ready for the hardest climb, and stoutest pull, and it was a pleasure to note the pride which all in the family seemed to feel in these horses. I believe the horses felt the appreciation. It is a united family, and the horses may be counted in.

The other man's horse had ribs—great, big ribs—twenty-eight of them all standing out in boldest relief. He also had a sore shoulder. The feeding was not prompt, was not regular, was, I dare say, at times omitted entirely. This horse did not seem in love with life. Were I his master I should fear he did not love me. I am sure I should take no pride in driving him. And I hope I should have disturbing dreams, in

which the 5th "Beatitude" and the Golden Rule would play a conspicuous part. I doubt if this horse was uncinched in the rest times, as he bore his owner or other up the steep mountain sides. "Old Don" refused to draw his load as he came to the "steep-est, hardest climb. He seemed to say, "I can't do it; it is too hard."

I wish again to repeat the lines of Eliza Cook:

"Oh, if to us one precious thing
Not theirs—a soul—is given;
Kindness to them will be a thing
To bear it up to heaven."

MUSIC IN THE HOME.

I wonder if we all appreciate the added charm that music gives to the home. Charles Darwin made the lamentable confession that, whereas he, as a boy and young man, was very fond of music, art and poetry, he gave his life so exclusively and so energetically to scientific research that he lost his love and taste for the other things. He did such grand work in science that we may the less regret the atrophy of the other qualities. He regretted this withering-up process, and said that were he to live his life over, he would give time to cultivate these other desirable faculties of his being. Does not the parable of the talent and the napkin urge us to round out our being and lives by cultivating all our faculties? I have had a somewhat similar experience to that of Darwin, and I also regret it. In my early life I was not only very fond of music, as I am still, but I quickly learned music. Hearing a piece sung once or twice, would make me able to sing it correctly. My daughter now sings, and some of her pieces delight me beyond expression. Yet, though I have heard them sing a score of times, I can not sing them. Were I to live life again, I should keep this music in my soul, rich and full. I have missed much.

Again, I know of several who seemed to have little taste or aptitude in music, who, by study, have become fine musicians. Music is so rich a gift and so priceless an adornment in the home that its cultivation may never wisely be neglected. It refines performer and listener. It gives the healthiest and best recreation, the keenest and most wholesome entertainment. If anything will fasten the love of children in the home, and stay their footsteps from wandering away, it is music.

I wish all our home circles might be the center of fine and oft-recurring concerts, that all the members might be the more knit into one bond of love and good fellowship.

DESKS FOR GENTLEMEN AND LADIES!

Combined Desk and Book-Case
Size, 66-in. high, 36 in. wide,
19 in. deep.
Price, \$13.75.

THESE DESKS are made of quarter-sawed oak, first-class finish, well put together, and will please every purchaser. They are an ornament to any home, as well as being a useful necessity. Would make a FINE GIFT for father, mother or sister.

The Combination Desk and Book-Case

is just the thing for a farmer or business man of any kind, to keep his private papers in, and for his books, etc. The drawers have locks, and there are a number of pigeon-holes inside each of the desks shown herewith.

The low prices quoted are f.o.b. Chicago. Send for free catalog. Address,

The Royal Star Combination

To Our Shippers :

We were obliged to notify you a few weeks ago that one Joseph M. McCaul had leased our old quarters at Nos. 120-122 West Broadway, New York City, and had there started up business under the name "HILDRETH, McCaul Co.," and had distributed a multitude of circulars so worded as to create the impression that his business was a successor to or a branch of the business of Hildreth & Segelken.

For the protection of our shippers and ourselves, we at once instructed our attorney to commence action to enjoin the said McCaul from using the name HILDRETH in any manner whatsoever in connection with his business. On the 10th day of July, 1901, Hon. David McAdam, Justice of the Supreme Court of the State of New York, after a full argument upon the merits, issued a peremptory injunction, of which the following is an extract :

"And it appearing that the plaintiffs have for a long time been and now are carrying on business under the style of 'Hildreth & Segelken,' and that the defendant has recently opened a business at 120-122 West Broadway, in the Borough of Manhattan, City of New York, and is carrying on the same under the style of 'Hildreth, McCaul Co.,' and that such act is in violation of the plaintiffs' rights, and that the commission or continuance thereof, during the pendency of this action will produce irreparable injury to the plaintiffs: it is

ORDERED that the defendant (Joseph M. McCaul) and each of his agents, servants and employees and all other persons acting under his authority and direction be, and he and they are hereby restrained and enjoined from showing, displaying or otherwise using during the pendency of this action in or upon any papers, devices, sign or signs, or otherwise, in the business conducted by the defendant at No. 120-122 West Broadway, in the Borough of Manhattan, City of New York, or elsewhere the name of "Hildreth" separately or conjunctively with any other name, designation or description."

Outside of our desire in our own interests to protect the name which we have built by years of satisfactory dealings with our customers, we hastened to procure this injunction as soon as possible, to prevent our shippers from being misled into sending their goods to one who would make an attempt to gain their trade by such a trick and device.

With thanks for the many expressions of good-will we have received from our shippers concerning this attempt to trade under our name, we are,

Sincerely yours,

HILDRETH & SEGELKEN,

265-267 Greenwich Street, NEW YORK, N. Y.

Bees Did Fairly Well.

The bees did fairly well here the forepart of the season on white clover, but it all dried up. We did not have any rain for three weeks. It has rained now, and I think we will have some luck with honey yet.

JOHN C. STEPHAN,
Monroe Co., Wis., July 26.

From an Amateur Bee-Keeper.

Number 30 of the American Bee Journal is just at hand; it is a splendid paper, and I would not be without it. I have taken it for four years now. Although I am an amateur I take great pleasure in its columns. I now have about 25 colonies, with 12 of them in old boxes of all sorts, and from which I get very little honey; but I have taken about 70 pounds from some of the others this season—all alfalfa honey. J. ROY BRADSHAW,
Humboldt Co., Nev., Aug. 2.

Drouth and Little Honey.

There is but little honey in southern Iowa, and in Missouri I think it is still scarcer. I had about 1,000 pounds from colonies enough I have stored 3,000 in a good season. The gathering came to a sudden stop in the early days of July. I have had swarms some seasons as late as July 15 that filled the brood-frames of a Jumbo hive. Our July was the hottest and driest anybody remembers. No rain from June 21 to July 28. We are having some rain now. Corn will make less than half a crop. Potatoes and garden vegetables are wiped out. Swarming was quite free in June. I will have to feed some of the swarms now. I am hoping for a fall flow. If it does not come I have the choice of heavy feeding or starved bees. EDWIN BEVINS,
Decatur Co., Iowa, Aug. 9.

Bees Have Done Well.

My bees have done well this season, giving me a nice surplus of white honey, with the fall flow now commencing, and prospects good. E. B. THRELL,
Genesee Co., Mich., Aug. 12.

Bees Selecting a Home Before Swarming.

Rip Van Winkle says, on page 429, he does not think that bees select their future home, for certain reasons. And I know they do, under certain conditions. Still, as a rule, they do not.

Years ago I kept bees in Canada, in box-hives. All increase was by natural swarming. When the hives became crowded I raised them on blocks at the corners. The day before a first swarm issued, the bees that were clustered on the outside of the hive would go into the hive, fill themselves with honey, and pack closely in and under the hive. I had a colony prepare for swarming, and it set in to rain, and continued more or less cold, windy and wet for eight days. Then the bees swarmed, and went directly to their selected (or where they selected) tree stood. The sun came out for half an hour the day previous to their swarming, and the scouts went out and selected the tree. I had two more colonies, and they reported that they had found a swarm of bees. So we cut the tree down, and not a bee was there. It was raining lightly when we cut it down. In that case the bees all let go at once, almost like emptying a bucket of water by turning it upside down. They never even stopped to circle about, but went straight for their selected tree, and were hazed about for quite awhile, and finally clustered.

The Emerson Binder

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

tered, and we lived them and took them home.

Another similar case was in Iowa. A swarm was prepared to come out, but the weather turned bad for eight days, and when they finally came out, they left in just such a hurry. I ran about a mile into the woods and came up to them as they were going into their tree. They could be heard by their loud hum or roaring at a distance of ten rods. I ran in the right direction, and then would stop and listen. The last run I made I passed them about six rods. Of course I cut down the tree at once, and took them home.

A man at Tusin reported a swarm of bees in his pile of fruit-boxes; that was four years ago, and he wanted me to get them, so I went, and no bees were there. But they came the following day. The man saw the scouts there, and supposed they had already taken possession. They were probably scouts from a clustered swarm. I do not believe one swarm out of a thousand looks up its locality before clustering in this climate, as there is no necessity for it on account of the weather being always favorable.

I found a swarm on the 19th of last April. They had been clustered for two days, had daubed the limb of the tree where they clustered all white with wax. I now have eight colonies. DR. E. GALLUP.
Orange Co., Calif., July 15.

No Rain for Over Two Months.

There has been no rain in this vicinity in over two months, and corn is ruined; there are few vegetables, and bees may have to be fed for winter. Water in wells and cisterns is giving out, and fruit is scarce. Honey will bring a good price, or should do so.

E. T. FLANAGAN,
St. Clair Co., Ill., Aug. 7.

The "Jouncee"—by the Original Jouncee.

Upon receipt of the American Bee Journal for July 5, I was a little surprised—gratified more than a little, and actually felt flattered over the kind words that Mr. C. Davenport uses in his enthusiastic praise of my quick method of getting bees out of an extracting-trap—via the "jouncee."

The "jouncee," in my practice, was devised for the purpose of quickly riddling a shallow Heddou super of bees, and the crud affair illustrated in Gleanings in Bee-Culture some three years ago, worked so well that I made a neat, substantial device, constructed with a cloth tray upon which all of the bees were caught, reducing the killing of bees to a minimum, and getting them in such shape as to dump them on the top of the brood-frames instead of scattering them all over the ground.

It seems to me that three years after description is a long time to wait for beekeepers to catch on to such a very short cut.

But when I consider that my own enthusiasm over my device was somewhat subdued by the sort of half-way ridicule with which my statement in relation to its benefits were received by some of my brother bee-keepers here, I do not wonder, then, that only one man, so far as heard from, has taken kindly to it.

Perhaps the name "jouncee" has something about it that excites the risibilities, or the fact that the Rambler used it had some adverse effect. Any way, the bees are not shaken out, they are given a sudden, quick jar, or for a more euphonious word, "jouncee," and the device, a "jouncee."

I have used the principle more or less for the past few years, and have kept mum about it for about three years.

When I left my own apiary in the southern end of this State, in charge of other parties, I had some misgivings about turning over my "jouncee" to them. As the parties were very sensible young men, I ran the risk, first showing them by practical demonstrations the use of the device and its effects. After the extracting season had well advanced, I received a letter from the parties, saying, "We are falling in love with your shallow super and the 'jouncee.' That settles it as far as the Shaffner Bros. are concerned; they know a

A Superior Red Clover Queen

(AN UNTESTED ITALIAN!)

For sending us One New Subscriber and 25 cents (\$1.25 in all.)

We arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us in this season. His bees average quite a good deal the longest tongues of any yet measured. The breeder he uses is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

All queens guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

We would like each of our present readers to have one or more of these fine Queens. Simply send us the name and address of a new subscriber for the American Bee Journal for one year, and 25 cents extra, and the Queen will be mailed to you. Our queen-rearer is now caught up with orders, and expects to be able to mail them hereafter within 14 hours after we receive the order. He is in another State, and we will send him the Queen orders as fast as we get them at this office. He is prepared to rear and mail a large number.

The cash prices of these Queens are \$1.00 each; 5 for \$4.75; or 6 for \$5.00.
Send all orders to

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

good thing after they have used it, and have gotten rid of the slow process of brushing bees from the combs.

It is just possible that others besides Mr. Davenport have used the plan, or have tried to use it; perhaps a comb or two has broken down in the first attempt. I think they are more likely to break in a frame deeper than the Heddon that may have condemned the plan in their estimation; but what if a comb does break now and then, has there not been an immense saving of time? And the more the plan is used, the more skill acquired and less combs broken.

I think Mr. Davenport is entitled to some credit for the use of the principle, for I have used it only on shallow supers, while he goes further and uses it on deeper frames. Any way, I hope the plan will be useful to other bee-keepers. J. H. MARSH, Fresno Co., Calif.

60 Pounds Red Clover Per Colony.

G. M. Doolittle says in the Progressive Beekeeper:

For the past 20 years red clover has failed to blossom in central New York, owing to an almost infinitesimal insect which works in great numbers in each head, just before the blossom would appear. This causes the head to harden and no blossom to open. But this year, owing to our continued rainy weather, or some other cause, we had fields red with clover bloom again, and when the hot weather came on the bees began to roll in the honey at a rate never known here before, outside of a good basswood yield, and for three or four days it was equal to any basswood yield. I could leave combs of honey out in the beeyard all day long and not a bee look at the honey, though several might be seen collecting propolis off the ends of the frames where they come in contact with the hive. And as brood-rearing was pretty good, 37 days before this clover yield began, from 60 to 70 pounds of section honey is the result from colonies which had not been robbed of bees and brood to make nuclei with, to rear queens for the trade.

I think I hear some one asking about the "long tongues." Well, I have not had time to have any measurements taken, as I have been too rushed this season hardly to sleep nights, but if any have long tongues all must, as I see little difference in the working of any colony which was in a proper condition to work. And this from the first crop of red clover. The most complained of these having red clover queens is that they work on the second crop, that having shorter corollas than the blossoms of the first crop.

The Root German Steam Wax-Press.

This is now put upon the market by the A. I. Root Co. Copying after the Germans, who have been ahead of us in this matter, a very substantial wax-press has been completed, which is perhaps an improvement upon any in Germany. It is of large size, holding more than a bushel of comb at a time. Its manipulation is given in Gleanings in Bee-Culture as follows:

To use, the can is placed on a common stove, and is filled with about three inches of water. The wire-cloth basket is filled with old comb, slungum, or any wax refuse. The water is brought to a boil, when the basket with its contents is set down into the can. The handle is unscrewed until the pressure-plate rests against the cover-plate. This is then set down on top of the can, and the water is allowed to boil. The steam generated passes all through the mass, and when the wax in the basket settles down, more refuse is put in. After all the free wax is

steamed out, the screw and plunger-plate are turned down. One person grasps the two handles of the can, and another one turns the screw down until a tight squeeze is exerted. It is then left for a little while when another

all along to keep up brood-rearing, and sometimes we get some surplus, we again go through all; and, taking off the top (or third) story, we go through the brood-chambers, putting all combs with honey in the top, or

squeeze is applied, and so alternately for a period of 15 or 20 minutes. The screw is then raised up, and the slungum is poked over with a stick, and again pressure is applied. By this time every particle of wax is pressed out. The basket is dumped, and the operation is repeated as before.

It is advisable to use a sheet of burlap or cheese-cloth to line the inside of the basket during the process of rendering, otherwise the cocoons will be forced between the meshes of the coarse wire-cloth. A finer mesh of cloth would not stand the enormous pressure, and hence burlap or cheese-cloth in connection with a coarse wire-cloth should be used.

Comb and Extracted Honey from the Same Hive.

Louis Scholl, as he tells in Gleanings in Bee-Culture, produces both comb and extracted honey from the same colony. He uses divisible brood-chambers, and early in the season (which in his Texas climate is in February) he sees that each colony has sufficient stores and a good queen. He says further:

After all are in proper order they are let alone for a few weeks; and when the weather is warm and favorable, and honey coming in we generally have enough honey coming in

Catnip Seed Free!

We have a small quantity of Catnip Seed which we wish to offer our readers. Some consider catnip one of the greatest of honey-yielders. We will mail to one of our regular subscribers one ounce of seed for sending us ONE NEW subscriber to the American Bee Journal for a year with \$1.00; or will mail to any one an ounce of the seed and the American Bee Journal one year - both for \$1.30; or will mail an ounce of the seed alone for 50 cents. As our stock of this seed is very small, better order soon.

Please Mention the Bee Journal when writing Advertisers.....

the third super, and all the empty combs in the two chambers of the brood-nest, arranging the combs so as to spread the brood, and to push brood-rearing, as we want a great force of bees just at the beginning of the main flow, which with us is about the first of May. The other super, containing the combs of honey, is now set on top. This operation will generally be done at about swarming-time in the month of March, sometimes sooner or later, depending on the earliness or lateness of the season; and at this examination, if some colonies are overpopulous, combs of hatching brood are taken from them and used either to strengthen weaker colonies or for making nuclei. If some of the colonies have already started queen-cells they are destroyed or otherwise as the case may be. I have already said something about swarming; but with such a large brood-chamber, and providing plenty of room for the queen, there will be very little if any swarming; but I gave the foregoing for the "exception."

Now comes the time of our main flow, which is just beginning; and if everything has been favorable we shall have strong colonies with a large force of bees; and, besides having had plenty of honey for breeding purposes, they will have some surplus stored in the shallow extracting-super above.

We must now hurry and get on the comb-honey supers, so taking the section-supers, which we had all nice and ready, with foundation in the sections, and an extra Danzenbaker reversible bottom-board, we proceed as follows:

First set one of the section-supers down, and on this set the upper (or third) case of the hive, without removing the cover. Then move the two lower chambers, bottom-board and all, to one side of the stand, and in its place put the extra Danzenbaker bottom—the deep entrance-side up—putting on this the upper one of the two brood-chamber cases, and on this the lower one, thus cutting the brood-nest in two, thereby putting the honey in the upper frames in the center of the brood-nest for the bees to reach, while the upper frames now contain brood.

The two other supers, the section super with the extracted-honey super above it, are now set on top of the brood-chamber. Here are two features with which I am greatly pleased; namely, in having bees first used to storing in shallow extracting-supers; and when the section-super is put in between this and the brood-nest, they go right on to work in the sections without losing any time; and I have also found that nicer and fuller boxes of honey can be produced between such a super than where the cover is directly over the sections. Then by using shallow extracting-supers during the time before the main flow, as we have honey coming in nearly all the time, and sometimes a little more than is needed for brood-rearing, it is stored in these supers, leaving plenty of room for the queen, while otherwise it would have to go to waste or the bees would store it in the brood-chamber, thereby crowding out the queen. With a set of these frames above, too, if a colony has more honey in the brood-chamber than is needed, the bees, when providing room, will carry the honey up into these frames, also bringing the brood up closer to the top of the frames.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Aug. 3.—For choice white comb honey the demand is equal to the receipts at 15c per pound, but all grades are slow at 1 to 3c less. Extracted is selling more freely at 13c; $\frac{1}{2}$ doz. for white; amber, 50c; $\frac{1}{2}$ doz. Beeswax steady at 30c. **R. A. BURNETT & Co.**

CINCINNATI, Aug. 10.—The honey market is rather dull on account of the warm weather. Extracted, selling at 13c; $\frac{1}{2}$ doz. at 50c; $\frac{1}{2}$ doz. at 50c; better grade alfalfa waterwhite from 60c to 70c; white clover from 60c to 70c. Fancy white comb honey sells from 13c to 15c. **C. H. W. WEBER.**

BOSTON, Aug. 3.—The honey market is practically nominal, demands being nothing owing to the warm weather. We have had one lot of new honey in that sold at 17c. Extracted, light amber, 8c; amber, 60c to 70c. **BLAKE, SCOTT & LEE.**

OMAHA, Aug. 8.—New comb honey is arriving by express in small quantities from Iowa and Colorado, and selling at \$3.50 per case in a retail way. California extracted honey is being offered carlots at 45c to 47c per pound, i. e. California shipping-points, but we have not heard of any sales having been made thus far. The production of extracted honey seems to be quite large this year in Colorado, Utah and California. **PEYCKE BROS.**

NEW YORK, Aug. 7.—There is some demand for new crop of comb honey, and receipts are quite numerous for this time of the year. They have been principally from the South, but we are now beginning to receive shipments from New York State and near-by. We quote: Fancy white, 11c; No. 1, 10c; No. 2, 9c; amber, 11c to 12c. No new buckwheat is on the market as yet, and we do not expect any before next month. Extracted is decidedly dull. Plenty offerings, with only a limited demand, and quotations are rather nominal. We are selling at from 50c to 60c, according to quality, and Southern in barrels at from 55c to 65c per gallon. Beeswax dull and declining; for the present we quote 27c to 28c. **HILGREN.**

DES MOINES, Aug. 7.—There is very little doing here in new crop of honey. Some small lots of near-by produced comb honey are on the market and selling in a retail way at \$3.50 to \$3.75 per case. We do not look for much trade in this line before Sept. 1. Our market does not consume a great deal of extracted honey. **PEYCKE BROS. & CHANEY.**

DETROIT, Aug. 12.—Fancy white comb honey, 14c to 15c; No. 1, 13c to 14c; no dark to quote. Extracted, white, 60c to 70c. Beeswax, 28c to 30c. **M. H. HUNT & SON.**

BUFFALO, Aug. 10.—Quite a good demand for fancy honey, 10c to 15c, and low grades, 12c to 14c, old neglected. Advise moderate shipments only as new as yet. **BATTERSON & Co.**

SAN FRANCISCO, Aug. 7.—White comb, 11c to 12c; amber, 8c to 10c; dark, 60c to 70c. Extracted, white, 5c to 7c; light amber, 4c to 5c; amber, 4c to 5c. Beeswax, 28c to 30c. The market shows the same quiet state as for some time past, bids of wholesale operators not being of a character to encourage free consigning from producing points. The German Steamer Hermonthes, sailing this week via the Cape Horn route for Europe, took 152 cases extracted honey, destined for Germany.

KANSAS CITY, Aug. 6.—Some very fine Missouri honey is now on the market, selling at 10c to 12c per pound for fancy white comb. Colorado and Utah shippers are offering new comb honey in carlots for first half of August shipment at 10c per pound for No. 1, and 9c to 10c for No. 2. Lost shipping-point. The market for extracted honey is as yet rather unsettled, asking prices ranging from 4c to 4 1/2c, i. e. 10c, shipping-point. Buyers, however, seem to be in no hurry to make contracts. **PEYCKE BROS.**

More Bee-Keepers' Paradises....

E. R. Root has just returned from a 6,000-mile trip through some of the best bee-locations in the world, and has already begun his series of write-ups, accompanied with fine photos, in Gleanings in Bee-Culture. The following editorial appears Aug. 1, and will give something of an idea of what he will describe:

Some little time ago I promised to tell about the bee-keepers' paradise in Texas. I have this on the docket, and it will appear as I take up the line of my travels. But since running across that paradise I have run into two or three others. There is one west of the Rockies, in Colorado, that is not yet overstocked with bees or bee-keepers; another one in Central Idaho—in fact, I do not know but the whole State. These will be described in turn. The fact is, millions of capital are being invested in irrigation; irrigation means alfalfa; alfalfa means a paradise for bees. But I found all along my trip that alfalfa-growing preceded bee-keeping by two or three years, for it seems to take about that length of time before bee-keepers find these gold-mines that have been hitherto unoccupied.

If you are dissatisfied with your present location, and for financial reasons, or on account of health, will be compelled to leave, subscribe for Gleanings in Bee-Culture, and learn something about the great South and the great West. There are many locations in the West that are not yet occupied—splendid bee-locations. If you wish to learn about them, send 25 cents for a six-months' trial subscription, or \$1.00 for one year and one untested Italian queen. Or, send \$2.00 and we will send Gleanings one year and one of our celebrated Red Clover Queens.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to interest the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one (of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we are furnishing to bee-keepers. It has a pin on the underside to fasten it.

Price, by mail, 6 cents; two for 10 cents; or 6 for 25 cents. Send all orders to the office of the American Bee Journal.

Weekly Budget.

ANOTHER FIVE NAMES have been received the past week at this office to be counted toward the 1,000 that we are working for as the membership in the National Bee-Keepers' Association. The second thousand will come more easily than the first thousand, we believe. But let's get the first 1,000 before starting on the second. Here are the honorable five:

SAMUEL SWITZER,	JOHN M. SEILER,
JOHN C. STEWART,	P. MUNRO,
GEO. W. HAUBER,	

MR. C. P. DADANT AND WIFE made this office a pleasant call on Wednesday, Aug. 21, when on their way from a visit to Sturgeon Bay, Wis., where they had gone with Mr. Chas. Dadant (C. P.'s father), where he makes an annual stay to avoid the hay-fever which "gets" him every fall when he remains at his home in southern Illinois. The senior Dadant is now 84 years of age, and holds his health and strength exceedingly well. Mr. Dadant reports a fairly good comb-foundation trade the past season, though their honey crop was next thing to a failure.

HON. EUGENE SECOR, of Winnebago Co., Iowa, general manager of the National Bee-Keepers' Association, was recently nominated as representative to the next State Legislature from his district. He expects to be elected. But if he doesn't, he can still have his office of general manager for the bee-keepers, to fall back upon. This latter is a higher position, too, than the other one for which he is "trotting"—in our humble opinion.

MR. RUFUS PORTER, of Schuyler Co., Ill., although the inventor of the Porter bee-escape, has never used one about a hive in any manner whatever.

A VARIETY OF MINDS make up the readers of any periodical. The American Bee Journal is no exception. And the editor is likely to learn—sometimes in a very emphatic manner—just what some people think of him and the paper which he tries to edit.

But these things have never disturbed this particular editor, even so much as a slight bee-sting. He is trying to do what he considers his duty in furnishing a helpful, readable bee-paper every week, and so far as he has ability both financial and intellectual—he will continue to do his best.

We are led to say that much on account of having received several letters recently which indicated great dissatisfaction with certain departments found in this journal. Now we, personally (and we think that ninety-nine one-hundredths of our subscribers would agree), believe that there is not a department in this paper but what is helpful. Of course, with some of the opinions expressed all may not agree. But that is all right. Few people agree in every particular. We read several different papers not devoted to bee-keeping, and they have many departments that we

don't read at all. We don't feel compelled to read them, neither do we consider it our duty to write to the editor a complaining letter about them. It is our privilege to read whatever we like, and let the rest go.

Isn't it a little strange that certain so-called bee-keepers aren't real happy unless they can fling at somebody or something? Our experience has been that among the most unreasonable and cantankerous of them are found the little 234 fellows who think they are wonderfully wise.

Please do not misunderstand us—we welcome suggestions and criticisms that are sensible, and honestly intended to be helpful; but the kind that are sent in just to exhibit a mean spirit, or to show off some personal conceit or egotism, better be left unwritten, for they simply go into the waste-basket at once.

HONEY-BEES are winged merchants; they keep stores and sell their honey.

MR. JOCELYN S. MORALES, of Jamaica, has been asking for information concerning the Buffalo convention of the National Bee-Keepers' Association, Sept. 10, 11 and 12. He wants to attend. Good for Mr. Morales. We hope he will be present.

MR. W. E. BAKER's residence and apiary are shown on the first page of this issue. He has been keeping bees for about five years, and has been very successful with them. For the past three years or more his daughter "Allie" has had entire charge of the apiary. Mr. Baker being a carpenter and devoting only a portion of his time to the bees. However, his number of colonies has so increased that he has decided to devote his entire time, hereafter, to bee-keeping and market gardening.

There are 50 colonies of bees now at work in Mr. Baker's apiary, and 17 swarms have been hived since spring, and these are also doing good work. He is making a specialty of section honey, which sells readily in the home market at 17 cents per pound. White and sweet clover are grown abundantly in his locality, insuring a good crop of honey almost every year. By July 10 he had already taken 56 pounds of new honey from one colony. His average net profit per colony last year was \$10.50. He says in writing to us:

"I keep the American Bee Journal on my table, and find it of great benefit to me in my work. I also have all the latest standard works on bee-culture in my library, and I read and study them, too. I use the Langstroth hive principally."

NEW KINGS IN THE APIARY are constantly being reported. Just think how many have been furnished by others who have reported them in your favorite bee-paper.

But perhaps you are using some apiarian king—best ways of doing things with bees—that have never been reported, so far as you know. Why not describe them for the benefit of others who have helped you by their hints and suggestions?

The American Bee Journal is here to help all by recording the best things from all. What can you offer that has been helpful in your own experience?

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., AUGUST 29, 1901.

No. 35.

✱ Editorial. ✱

The Buffalo Convention opens a week from next Tuesday evening, Sept. 10, in the Lecture Room of the Buffalo Library Building, at the corner of Washington and Clinton Streets, near the business center of the city.

We are looking forward to the largest gathering of bee-keepers ever held in the East. Chicago has set the pace, there being about 500 in attendance at one evening session last year when the National convention met here. There never had been anything like it, we believe—at least not during the past eight years, as we have attended every national meeting during that time.

There are to be no papers read at this Buffalo convention. All the time is to be consumed in the discussion of questions. Such an impromptu program often proves to be one of the most interesting and profitable, when properly conducted. At least, the Chicago Bee-Keepers' Association has found it so.

But the main thing just now is to begin to get ready to go to Buffalo.

Pictures of Apiaries.—Some time ago we called for photographs of the apiaries of our readers, and quite a number have been sent to us. They will be used as time goes on. But we want more of them. If you have a picture of your apiary, why not send it to us? If it is not good enough to make a creditable engraving, we will tell you so, and return it, if you so request.

When sending, please remember to write your name and address on the back of the photograph, to avoid mis-takes after we get it. Sometimes we receive several at one time, and desire to use every precaution to prevent errors.

Too Much Room in Spring has made sad the heart of H. H. Hyde, as he relates in the Progressive Bee-Keeper. It is the custom in his part of Texas to leave all the extracting bodies on the hives during the winter, as the easiest way to take care of them. He says:

I had been drifting along like the balance, giving the question very little thought until this spring, which was a very late, cold, backward spring—the bees being very late and dilatory in breeding up. I very soon noticed that the single-story colonies, or such as had only as much room as they could occupy as needed, were outstripping those that had a large surplus in room. Single-story colonies soon built up strong and ready for the honey-flows, while the others were dragging along,

and for a good part of the time only holding their own, the result being that when the honey-flow came on they were weak and in no position to harvest the honey crop. I think that this has taught me a valuable lesson, and it should teach a lesson to every one else in this part of the country.

It is not difficult to understand why a colony should not do well in winter or early spring with a large empty space above it. It is too much like being outdoors. Heat rises, and in the winter time a thermometer will show the upper part of a living-room several degrees warmer than near the floor. If it is thought desirable to have vacant room in cool or cold weather, let it be below and not above.

Some Big Reports are assembled in The Pacific Bee Journal, including just a little to discourage bee-keepers in regions less favored than California. Emerson Bros. increased from 825 to 1,000 colonies, and took 40 tons of honey. C. A. Pyle increased 70 colonies to 102, and took 14 tons (400 pounds per colony.) J. B. McLure started in the spring with 29 colonies, and took 45 tons. A. Joplin with 225 colonies took 21 tons. G. Dombrowsky took 14 tons from 170 colonies, spring count. Mercer & Son, 50 tons from 525 colonies.

The Price of Honey is something that the bee-keeper sometimes finds it hard to settle upon. He is at a loss to know what price he should put upon his product when selling to a grocer or a private customer. It is a clear case that if he is to hold the trade of the grocer it will not do to sell to private customers as low as to the grocer, and it may be the better way to sell at retail at the same price as the grocer. But what shall determine the price to the grocer? G. M. Doolittle, in a conversation in Gleanings in Bee-Culture, discusses the matter very sensibly as follows:

Find the quoted price for each grade of honey which you have, in the city to which you would send your honey, did you ship any way, and then figure the expenses for freight, cartage, and commission out, and you will have what it is worth at your nearest railroad station. For example, the rates on comb honey from Skaneateles to New York City is 50 cents per 100 pounds. As this is gross weight, we find by a little figuring that about 55 cents per 100 pounds is what the freight will cost, and the cartage will bring it up to 80 cents. Quotations during the months of July and August are generally little more than nominal; but from them we will guess that fancy honey will bring from 12 to 15 cents this year. But unless our honey is exceptionally fine I should not put it above 14. Then as most commission men charge 10 percent for selling, we have \$8.40 as the cost of selling 100 pounds. This, added to the 60 cents freight and cartage, makes a cost of about 2 cents per pound to get our product to market, and the cash for it in our possession,

so that, on the basis of these figures, if you can not sell the honey you have in Skaneateles and surrounding towns at 12 cents per pound, you had better send it to New York."

Well, I had never thought of reasoning it out in that way. I thought I ought to have 13 cents for it, or only one cent less than New York quotations."

"It is an old saying, that 'a nimble sixpence is better than a slow shilling,' and I fear you will find that your honey will go very slow at 13 cents, while it would sell rapidly at 12 cents. Then there is a possibility that, when the market comes to be established this fall, honey may go still lower than the nominal prices we have used, in which case it would be better to move it off rapidly by putting the price at 11½ cents, where a party would take a whole crate."

One phase of the case, however, Mr. Doolittle does not touch upon. In some places and in some years it happens that the local supply is so short that grocers send to the large cities for their supplies. In that case the bee-keeper would be foolish to follow the same rule as in years of full supply. It may be that grocers in Skaneateles never send to New York for honey, but it is certain that grocers within 100 or 200 miles of Chicago often send to Chicago for their supply. For the sake of illustration suppose the same thing should occur at Skaneateles. The crop is short, and the bee-keeper, following the general rule, sells to the grocers the few hundred pounds he has at 12 cents, the New York price being 14. When these few hundred pounds are exhausted, the grocers must send to New York for a further supply, paying 60 cents per hundred freight, making the cost a little more than 14½ cents per pound. By what rule of right should the bee-keeper sell to the grocer for any less than this price? If he sells at 12 cents he is losing 2½ cents on every pound he sells. So when the crop is so short that part of the grocers' supply must be secured from the large cities, the rule should be, not to deduct freight, commission, etc., from the city price, but to add to the city price the amount for freight.

Foundation Splints (instead of wiring brood-frames) have been warmly advocated by some bee-keepers. Splints about one-sixteenth of an inch thick are soaked in hot wax for the purpose. B. F. Averill says in Gleanings in Bee-Culture that he does not find it necessary to have the splints coated with wax. He merely presses the wooden splints into the foundation, having them longer than the inside depth of the frame so that the end of the splints rest in saw-kerfs in the top and bottom-bar. They are put alternately on opposite sides of the foundation, six or seven to a frame, and no other fastening for the foundation is needed. One advantage is that the foundation is built right down to the bottom-bar.

A Trio of Questions—Bee-Book Reviews.

BY PROF. A. J. COOK.

I REGRET if any have questioned the wisdom or courtesy of my reviews of the bee-books. I believe we all—Dadant, Cowan, Root, and myself—wish only the truth. If we have made mistakes—and, of course, we all have—we are only too thankful that they be corrected. I always rejoice with exceeding joy at any kindly criticism of my books, or my journalistic articles. As Mr. Root says, I am not always right. If any earnest student thinks me wrong, I like to know, that I may re-examine, re-test, and very likely find I am in error. Then how quick I will be to correct. I am sure all our authors in question are of like mind.

There are two good reasons why these criticisms should not be withheld, viz:

1. It brings mooted questions before us to be studied and rightly decided.

2. Though possibly corrected in latest editions, the hosts have only the older editions, and surely they are entitled to have their text-books corrected.

BEES EVAPORATING HONEY IN TRANSIT TO THE HIVE.

The criticism of my position on this subject warrants reply. Surely, I seem to be almost discursive and dogmatic, when I say, "I know bees never do this." I do not mean to call in question the truthfulness of those who claim to have seen the falling mist. I have never seen it, though I have tried to discover it often. When I say, "I know," I refer to the appended theory, "Evaporation of the nectar." If some one should report seeing a bee carrying a large substance, and should add that he believed it an iron wedge weighing a pound, I would have no right to doubt the first part of the statement. I would have a perfect right to say I know regarding the second part.

The water of nectar holds the sugar in solution. It is a close integral part of the liquid. It can only be separated, so far as we know, by force, heat, or centrifugal motion. The bee can not possibly exert any of these on nectar within its honey-stomach. The statement of falling mist we may not dispute. The impossibility of evaporation we may affirm, and so say "we know." I repeat, if such droplets do fall from the bees, they are fecal, or respiratory—shall we say sweet atoms?

KILLING BEES TO STING.

I also speak with a sort of offensive dogmatism on this point. I have over and over suggested to my students to perform the following experiment:

With a glove on anger the bees, till a dozen, more or less, sting the glove, and actually pull out their stings. Then they were to catch as many from the combs by taking hold of the wings. Each lot was put into a cage provisioned with honey or "Good" candy. In a few days *all* of the first lot would die, while *all* of the others would live for weeks. Often the second cage was peopled with bees taken as they were about to fly from the hive in quest of nectar.

This explains why Mrs. Clark's bees that stung her cow to death were so generally destroyed. She reports that her apiary was seriously depleted, while thousands of bees were dead near the carcass of the cow. We all know that bees may sting and not lose the sting. Of course, such cases may not prove fatal.

SCIENTIFIC USE OF TERMS.

The dictionaries are conservative. They allow expressions which expert usage would not permit. Physiologists do not confound digestion and assimilation. It would not be exact, and so would be unscientific to do so. Is it not wise to go to the best and latest specialists in physiology for our definitions? If we do so we will say that digestion is to fit the food for absorption; and that assimilation has to do with metabolism or tissue changes. The entomologist is wise in not calling a larva a worm, for it is not. The entomologist might possibly use the term miller for moth; it would be rare, however, but he surely would not

say moth-miller. He would as correctly speak of a female woman. Are we not wise to consult the up-to-date specialists in our use of scientific terms?

Valueless Figures as Applied to Bees—In-Breeding.

BY G. M. DOOLITTLE.

FREDERICK B. SIMPSON is one of the comparatively new writers for the bee-papers, yet his articles are full of life and "spice." I have read them with much interest, and hope he will continue to write more and more, especially so as he may gain more and greater light on many of the vexatious problems with which apiarists have to deal. I judge from his writings that he is more thoroughly conversant with the vexatious problems relating to horses, than he is with those relating to bees. But if his life is spared he will doubtless learn all about many, if not all, of the bee-problems. And I bid him "Godspeed," that he may know of the height and depth, of the length and breadth, of this most fascinating, as well as often most vexatious, pursuit—bee-keeping.

On page 485, I find these words from his pen:

"In the American Bee Journal for June 20, Mr. Doolittle gave us some figures, but as he failed to notice that the mother of the drone with which a queen mates is entitled to probably the same share in the results [greater, in my opinion—G. M. D.] as the queen's mother, and also that the mother, or mothers, of the drones with which the breeding queen's daughters mate are also entitled to some share, his figures are of little value."

Just so. And even at the risk of appearing "sassy" I wish to say that his, "whereas the *real* cause of quality is skillful selection," and, "which qualities should be proved to be hereditary in each pedigree," as given in his "in-breeding" article, are equally of little value, as applied to bees. And all the illustrations which have been given in the bee-papers during the past 30 years, no matter by whom given, as comparing the breeding of horses, cattle, sheep, poultry, or swine, with that of breeding queen-bees, have been equally valueless, for there is no common ground (on which to stand) between them.

Suppose Mr. Simpson, with all of his horse knowledge, was obliged to turn his highly bred mare out into a 10,000 acre forest, filled with twice that many stallions of all grades, sizes and colors, she going way out of his sight and hearing before she met even a single one of them; of how much value does he think would be any words he could say about his "skillful selection," the "hereditary in each pedigree," or about the "mother of the stallion with which his mare mated?" The fact is, the breeder of queen-bees is "all at open sea" in this matter of the *selection of drones*, and all talk along the line of what drone any queen mates has no value attached to it whatever.

I have had a standing offer, out for years, of \$500 to the man or woman who would give me a *practical* plan whereby I could mate a queen-bee to *any individual* drone, with the *same certainty* that a horse-breeder could mate his stock. And I know of several other queen-breeders who would give from that to twice that amount. Here is your chance, Mr. S. And not only a chance to get the \$500, but also to receive the heartfelt gratitude of thousands of bee-keepers of the present age, and those who are to come after us during the centuries yet to come. And, until this problem is worked out, it is useless to talk about "hereditary," "variations, how started, intensified, and established," or anything of the kind. And the "great big tent" plan, lately agitated, should it prove successful, would not at all meet the requirements of the Simpson horse-breeders, nor claim my \$500; for that would be like turning out the mare, in the supposed case, into a forest containing from 50 to 1000 stallions, with the simple guarantee that they were raised from *one* mother. Some would be weaklings along some or all lines, lacking of proper form, proportions, etc., and would be something that no careful stock-breeder would ever listen to, although it might be somewhat of an improvement over the first, or what we now have.

Those who have accused the present race of queen-

breeders of simplicity, and lack of insight into matters which go toward making a scientific breeder of other stock, have failed, in that they have not taken this mating question into consideration as they should. I know that there are queen-breeders of the present time who have put as much thought into it, and spent as much time thoroughly to equip themselves, for their business, as any breeder of any of our domestic animals. And because they could not control the mating of their queens, is no sign why they should be classified with the ignoramuses in breeding domestic animals. This last is not thrown at Mr. Simpson, for he has treated the queen-breeders of the present very fairly, as far as I have seen.

And now I wish to say a word about that "in-breeding" matter. The reason, Mr. Simpson, why "the regular contributors to the bee-papers have not shown any desire to give us any specific aid on this subject," is, because, under the present state of affairs, there can not well be any *in-breeding* with our bees. With thousands and millions of drones, from scores and hundreds of hives, within a circle of five to ten miles in diameter, all congregating together, as the stallions in the forest, there is very little chance that any queen could possibly mate with a drone from her own mother. But suppose she did? Does not Mr. S. know that it would be only her mating with a *half-brother*? The drone is "the son of his mother," while the queen is the daughter of her mother and father. And as the drone is always, practically speaking, the son of his mother, in-breeding could be carried on for several generations, even with a full control of both queen and drone, before we could practically mate a brother and sister. And with the present conditions of mating, and with no chance at all of having "our say in the matter," it is simply folly for bee-keepers to talk about in-breeding, or to say very much regarding the mating of their queens any way, as to what drone she mated with.

The very best I have been able to do on the drone-side has been to keep a lot of drones from my best breeder, not nearly akin to the queen-mother, till fall, after other drones were killed off, then "hand pick" them, culling out all the inferior ones, when I had some reasonable assurance that queens reared at this time would mate with some of these drones, providing that some other colony within the circuit of the flight of "drone and queen," did not have a failing queen, or was queenless, in which case there would probably be hundreds of drones from such a colony to where there was tens of my hand-picked specimens.

I spent much of the time during the later seventies and early eighties in trying plans for the control of fertilization, thinking them out nights and trying them days, besides nearly all the plans advised by others, and after having to write "*A failure*" after each experiment, I settled down to try to do the best I could from the queen side, which thing I have been doing ever since. But I am free to admit, with Mr. Simpson, that if I could have had complete control over the drone which mated with any queen during all these years, there would have been more "value in the figures" than there is at present; although a yield per colony of from 60 to 80 pounds of comb honey from red clover this year, with little or nothing 20 years ago, proves that I have not labored entirely in vain.

Onondaga Co., N. Y.

No. 12.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

ONE of the most serious of the short-comings among those who keep bees on the farm is, that they don't know what to do with them in case of sudden emergencies. Robbing is one of the worst of these, please remember, Mr. Bond. Even if you reduce the present number of your colonies, as you now contemplate doing, down to one or two, you will need to be informed on this subject in order to be ready for business when the bees furnish the occasion.

"A few years ago I sold a colony of bees to a man who lives about a mile south of here. He said his wife was crazy to have some bees, but didn't know anything about managing them. But as he knew how, and wasn't afraid of them, he thought they could risk it to begin with one colony.

"Well, he took the hive I sold him home early in April. It was one of my best colonies. I instructed him how to

make the bees mark their new location, and how to manage when a swarm should issue—the colony having a clipped queen.

"A large swarm was secured all right some time during the month of May, and the queen taken care of according to directions. When it was time to put supers on I went and showed him how to put them on. All seemed to go well, except that no honey was stored in the supers, save a few pounds during the late season. I also instructed both of them one evening how to prepare the colonies for wintering, either outdoors, or in the cellar.

"Well, they thought 't would be a capital idea to try both methods of wintering, so he carried one hive—the one containing the new swarm—into the cellar, leaving the mother colony out in the cold. The phrase, 'out in the cold,' was severely emphasized by the fact—not known to me till the following spring—that my friend neglected to carry out my instructions as to how the hive should be prepared for the outdoor siege. He didn't even have time, he said, to take the super of nearly empty sections off before cold weather set in.

"One day in early April he came to me and requested that I should come and tell him what ailed his bees. The old colony, he said, was about played out, and the other hadn't seemed to act right since he had brought it out of the cellar.

"When I had finished examining those hives I found no queen in the latter, and not a spoonful of honey in the first, though I found a small and feeble-looking queen there. I told him to feed the honeyless bees at least a pint of syrup a day until fruit-trees were in bloom; and more if necessary. I furnished him a feeder and full instructions with it. But those bees were all dead when I saw him again—about two days later. His wife thought it was too expensive to feed bees so much syrup; and he, being more liberal, thought it took too much time. These points I got later, and from an outside source.

"I also furnished that man a frame of brood, put it in place for him, and cautioned him to watch the hive very closely until a new queen could hatch out. He didn't do it, although I had fully explained why it would be necessary. The result was that he lost that colony also, and as follows:

"One day, soon after giving him the foregoing advice, he sent me word by telephone to come up as soon as possible—the bees were robbing. When I arrived on the scene an hour later I found the reverse of his statement to be only too true: The colony had been robbed! Not only the honey was gone, but all the bees also.

"On inquiring for particulars, I learned that early that morning the colony seemed to be all right, and busily working—lots of bees in the hive," he said. Here, then, was an entirely new—new to me then—feature in this case of robbing. I couldn't conclude otherwise than that, after realizing that resistance was useless, or worse, that colony of bees made a full surrender, filled up with honey, as they do when about to swarm out, and went with the robbers in a body. This is not a groundless theory, but evidently a fact. There was no other sensible explanation, as but a few dozen dead bees were found near the hive, and none in it.

"Before I left for home I requested my friend to show me the place in the cellar where the colony had wintered. There I found the solution of the cause of the robbing: the dead queen on the cement floor of the cellar, among perhaps one-third of the bees, also dead! The foolish man had neglected to screen the bee-entrance, and had given the bees no ventilation in the hive; and he had also allowed too much light in that part of the cellar. And yet, to this day, those people can't understand how it was that I had an average, the previous season, of 75 pounds of honey to the colony, while they, only a mile away, and with two colonies of my bees, didn't get a pound!

"I have related this case in detail, Mr. Bond, to show how absolutely essential to success it is to attend to *all* the details in the management of even one colony. It is even more important when you have one or two only, instead of 50 or 100; because, if you lose one, or both, you are out of the business entirely."

"That's a very interesting case," remarked Mr. Bond; and instructive, too, as far as it goes. But in telling the story you failed to tell me just what you told your friend to do with those hives, to prepare them for winter, each in a different way and place. I think I ought to know those details," concluded Mr. Bond.

"I should have overlooked that fact if you hadn't mentioned it," I replied; "and it's the really valuable part of the story to you, too. Well, I can repeat the substance of

what I told that friend to do, and you can apply it next fall when it's about time to prepare your new colony out there for winter—either outdoors, or in the cellar.

"Be sure to avoid, at the outset, the too common mistake of waiting with the winter-preparation work until cold weather has set in. Here in Kansas it is generally safe to wait until the middle of October—seldom as late as November.

"The first thing you must do has to be done whether the colony is to remain on its summer-stand, or to be transferred to the cellar, and that is this:

"Prepare your bee-smoker as I have already shown you. Then you put on your bee-veil, remembering that at that season of the year the bees are much more touchy and liable to sting than during a honey-flow. Then you take your prying instrument and go out to your hive—smoker in full blast in your hand. If you prefer to quiet the bees before beginning operations you rap sharply a few times on the outside of the hive. Then you wait about five minutes for the bees to fill themselves with honey before you remove the cover in order to get at the super, which I will suppose you put on in time to catch the late surplus honey. This super you then take off, in the manner I have shown you, and set it, for convenience, on top of the hive-cover, where it is safe—if securely covered—until the rest of the job is done.

"You are now ready to loosen the ends of the brood-frames, with the tool you have brought with you for that purpose, blowing a little smoke over the top of them while doing so, should the bees crowd to the surface and get in the way.

"When this is done you begin the real business to which the foregoing was merely introductory; namely, you begin in the middle of the brood-nest and take out the frames, one by one, examining each in succession to find the queen. It is the queen you are really after, more than anything else, because the prime object of this whole performance is, to ascertain—not to guess at, as many keepers of bees do—the fact that the colony has a queen. It is very important for you to be sure of this, not because the colony couldn't live through the winter without a queen, for it can; but because they can't begin house-keeping operations in early spring without a mother-queen. You could not very well go through such an operation in February or early March in order to find out what you should know before you shut the hive for the winter. I hope you'll never forget that, Mr. Bond.

"Of course the fact will suggest itself that, after you have found the queen, and have estimated the honey in the frames to be fully sufficient to last them till spring, you replace all the frames and cover them snugly with a piece of fine burlap. You then put a rim—such as I use in tying-up supers—on the hive and pack the space inside with chaff or soft forest-leaves. Next you put on the hive-cover, placing a stone on top of it to keep it in place; contract the entrance-space to about the right width to suit the weather at the time, and your work is done for outdoor wintering in Kansas.

"For cellar-wintering you do no packing on top. Neither do you take the hive to the cellar before cold weather has begun. Then you remove the entrance-blocks and tack a piece over the brood-frames for the same purpose. Prepared in this manner your bees are safe in a dry cellar. But if the cellar is too cold—that is, below 45 degrees at any time—place a piece of burlap or a piece of old carpet over the screen on top of the frames. It will keep them warm without depriving them of needed air.

"I have kept bees both ways for years, and have never lost any in winter-quarters on account of cold, want of air, lack of food, or on account of inexcusable neglect.

"Here endeth the lesson."

Mr. Bond took dinner with us and then departed for home, taking his colony of bees with him, as happy as I had ever known a farmer to be.

(The End.)

Why Not Help a Little—both your neighbor bee-keepers and the old American Bee Journal—by sending to us the names and addresses of such as you may know do not now get this journal? We will be glad to send them sample copies, so that they may become acquainted with the paper, and subscribe for it, thus putting themselves in the line of success with bees. Perhaps you can get them to subscribe, send in their dollars, and secure for your trouble some of the premiums we are constantly offering as rewards for such effort.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editor.)

Mulberries for Bees.

What Dr. Peiro says on page 525 leads me to think that it is possible there may be two kinds of white mulberry, and if any one is thinking of planting largely it would be well to make sure of having the kind that he speaks of as bearing luscious fruit. In Pennsylvania I was familiar with the black mulberry, of which I was very fond. When I came to Illinois I found white mulberries growing wild (not in this county, but further south), but the fruit was insipid, and to my taste hardly fit to eat. I do not suppose it would be difficult to get bees to work on the crushed pulp of mulberries or any other fruit, but the question is whether what the bees would store therefrom would pay for the gathering and crushing. It would probably take a good deal to make old bee-keepers believe that bees could store good honey from the pulp of any fruit.

C. C. MILLER.

Milkweed Pollen-Masses on Bees' Feet.

I send a sample bee. By using a microscope you will see a foreign substance attached to its feet, which prevents walking or working. The other bees are pulling them out, and carrying them off in large numbers. What is it? What particular plant or flower do they get it from?

PENNSYLVANIA.

ANSWER.—The milkweed is the culprit—*Asclepias Cornuti*. The pollen-masses become attached to the feet to such an extent that the bees appear not to be able to climb upon the combs. At any rate, their sisters drive them out. It is possible that enough is gathered from the milkweed more than to pay for the damage done; at any rate the loss is not serious, and there is nothing you can do about it.

Loss in Introducing Queens.

A queen sent me arrived in good shape, and I introduced her according to directions, but the bees did not receive her. I have kept the colony supplied with fresh eggs to prevent laying workers, if possible, and to give them a chance to rear a queen, but the queen-cells they have started have all been with eggs that were too old. I examined them carefully before I introduced the queen, and destroyed all their queen-cells, and I am very sure there were no laying workers.

1. Do you suppose the presence of fresh eggs in the hive would prevent the workers from laying?

2. What is my trouble? NEW HAMPSHIRE.

ANSWERS.—1. Laying workers are not likely to occur if the bees are kept supplied with eggs or young brood.

2. In asking what is your trouble, you probably mean to ask what was done wrong that resulted in the killing of the queen you were trying to introduce. Perhaps there was nothing at all wrong on your part. The attempt to introduce a queen is not always successful. Nineteen queens out of twenty may be accepted all right and the twentieth rejected, although exactly the same plan was used with the twentieth as with the other nineteen, and no one can tell just why the twentieth failed. I don't understand what you mean by saying they started queen-cells with eggs that were too old. When bees are without a queen they rarely start queen-cells from the egg; nearly

always from larvæ; and an egg could not be too old unless dead. Neither would they start a queen-cell from too old a larva if constantly supplied as you say with fresh eggs. But the presence of eggs and young brood would be no help toward the acceptance of a queen, for they might think they could rear a queen of their own, and thus reject the one offered.

If you want to take the trouble, you can make the acceptance of a queen a sure thing. Take two or three frames of just-hatching brood, with no unsealed larvæ, put them in a hive without any bees, put in the queen and shut the hive up bee-tight, and keep it for five days in a warm place in the house, or over a strong colony with wirecloth between, so that the heat but no bees can pass up through. You can make sure of frames of the right kind of brood by putting frames of brood eight days in advance in an upper story over a queen-excluder.

Late Swarming.

July 25 I opened hive No. 1 and killed the queen; July 27 I gave a new queen to the colony, and Aug. 10 this same colony swarmed. I caught the queen and had the bees to return to their hive. Two days later I opened the hive and found one queen-cell; I cut it out, and handed it to my daughter, when, to her surprise, the queen left the cell and

was born, as it were, in her little hand. I caged the young queen and returned the old one.

1. Now, why did they swarm so late, when the flow is almost over with us here in Pennsylvania, and starvation staring them in the face?

2. Is the young queen of any value to me, as I see no drones flying any more? PENNSYLVANIA.

ANSWERS.—1. You do not say whether you know that the queen which you caught Aug. 10 was the same one you introduced or not. It is possible it was the same, and that the bees were nearly ready to swarm when you introduced her, but the break in laying postponed their action. The flow being near its close would not hinder the swarming, so long as the flow continued, for the bees might expect it to continue indefinitely. If, however, it was a normal prime swarm, the old queen issuing with the swarm, a young queen would hardly have issued from the cell so soon as two days after the issuing of the swarm. It is more likely that the queen you introduced was killed, and that a young queen issued with the swarm, for when young queens are reared upon the killing of a queen, the colony is likely to swarm when it might have had no notion of swarming if the old queen had remained. Bees seem to be more reckless about swarming with a virgin than with a laying queen.

2. The young queen is probably all right. Even when you think all the drones are killed off, a few are still likely to be flying until cold weather actually comes. Indeed, they are sometimes allowed to go into winter quarters.

Fall Transferring.

I have several colonies of bees, purchased in box-hives, and I want to transfer them to dovetail hives. Would you advise me to do so immediately, or would it be preferable to wait until spring? CALIFORNIA.

ANSWER.—You will probably do well to wait till spring.

An Introducing and Swarming Experience.

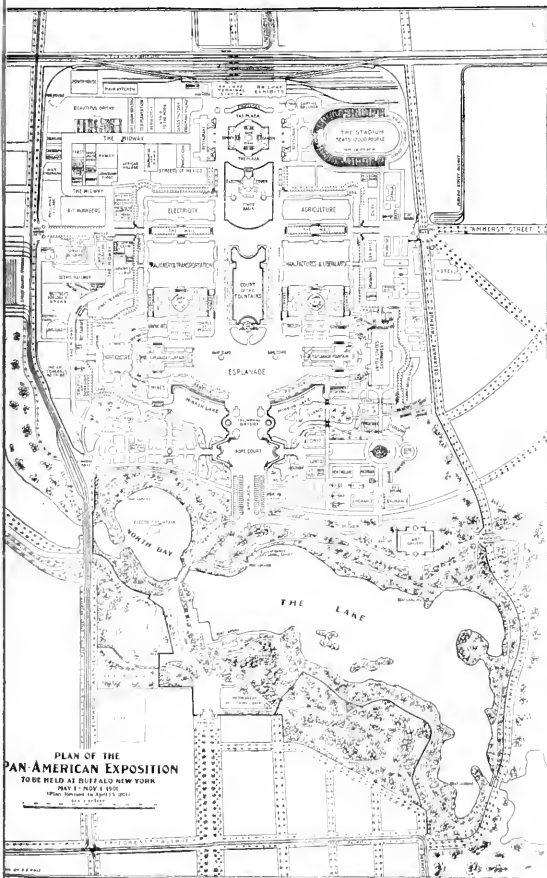

1. I had a colony swarm a week ago (June 15.) and when I hived them everything seemed to go all right. But, alas, towards evening they killed their queen, so I let it stand a day and I introduced a laying queen. But they killed her, too, so I was almost crazy, because it was a valuable queen. So I got a little hybrid queen, laid her above the frame for a day, and then I put her in an introducing-cage, but they would not eat her out. So I let her out myself, and she went to laying. Now the point is this: Yesterday they cast a big swarm. What was the object of their swarming? They had the old queen with them, because she was clipped. They have five sealed queen-cells. They had supers on, and lots of ventilation, and they had not worked in the super very much.

2. Do you think they will go right to business? There was a flow from basswood and button-ball. ILLINOIS.
